## CANDIDATE'S DECLARATION

I hereby certify that the work which is being presented in the thesis entitled "OPTIMAL WATER UTILIZATION AND INTRA-BASIN WATER TRANSFERS IN CAUVERY BASIN, INDIA" in fulfillment of the requirement for the award of the Degree of Doctor of Philosophy, submitted in the Department of Water Resources Development Training Centre (WRDTC), Indian Institute of Technology Roorkee, Roorkee is an authentic record of my own work carried out during the period from July 2000 to March 2004 under the supervision of Prof. Nayan Sharma, WRDTC, IIT Roorkee and Prof. D.K. Srivastava, Department of Hydrology, IIT Roorkee, Roorkee (India).

The matter embodied in this thesis has not been submitted by me for the award of any other degree in this or any other institute.

(M. D. PATIL)

This is to certify that that the above statement made by the candidate is correct to the best of my knowledge.

(NAYAN SHARMA) Professor, WRDTC

HT Roorkee, Roorkee

~~~~

(D.K.SRIVASTAVA)
Professor, Dept. of Hydrology
IIT Roorkee, Roorkee

Date: March, 2004.

The Ph. D. Viva-Voce examination of Mr. M. D. PATIL, Research Scholar has been held on 13.69-2004.

#### ABSTRACT

According to the National Water Policy 2002 of India, water resources development and management will have to be for a hydrological unit such as drainage basin as a whole or a sub-basin, taking into account surface and ground waters for sustainable use incorporating quantity and environmental considerations. All individual developmental projects and proposals should be formulated and considered within the frame work of such an overall plan keeping in view the existing agreements/awards for a basin or sub-basin so that the best possible combination of options can be selected and sustained. Water should be made available to water short areas by transfer from other areas including transfers from one river basin to another, if necessary, based on a national perspective, after taking into account the requirements of all areas/basins. Integrated and coordinated development of surface water and ground water resources and their conjunctive use, should be envisaged right from the project planning stage and should form an integral part of the project implementation. Irrigation intensity should be such as to extend the benefits of irrigation to as large a number of farm families as possible, keeping in view the need to maximize production. Irrigation being largest consumer of fresh water, the aim should be to get optimal productivity per unit of water. In view of the vital importance of water for human and animal life, for maintaining ecological balance and for economic and developmental activities of all kinds, and considering its increasing scarcity, the planning and management of this resource and its optimal and equitable use has become a matter of the utmost urgency.

The Cauvery is an inter state river in South India originating in the state of

Karnataka and flowing through the states of Karnataka, Kerala, Tamilnadu, and Pondicherry having a catchment area of 81,155 Km<sup>2</sup>. This basin has 16-sub-basins. It has 75% and 50% water year dependable surface water potential of 16,470 MCM and 20,776 MCM, respectively. The total of 3,866 MCM ground water potential is available for future use. The water requirement for the population of human and livestock projected to the year 2050AD for all purposes as estimated is 39516 MCM. There are 15 major reservoirs and 58 medium and a large number of minor irrigation projects in the basin. The total irrigable area is 2605200 Ha.

The sharing of the water resources of the Cauvery river is under dispute between Karnataka and Tamilnadu for a long time and creates a law and order problems in the states. The issue has been referred to The Cauvery Water Disputes Tribunal (CWDT). The purpose of the study is to find out the technological and realistic solution for the problem. The optimal allocation of surface water and ground water is therefore necessary so as to optimize the annual water utilizations for irrigation, domestic, industrial, hydropower and environmental uses. The interim award of CWDT (CWDTIA) is to release 5800 MCM (205 TMC ft) of water from Karnataka to Tamilnadu at Mettur reservoir.

To identify water surplus and water deficit basins, water balance studies are generally carried out on an annual basis, and are usually done on a lumped basis. They also do not take into account many important aspects, which influence the water balance of a river basin to a large extent. In the present study, some of the most important among them are considered for the water balance study, and two of them are (i) the timewise variability and distribution in the surface water availability and its use with respect to the yearly and the within year time periods, and (ii) the availability and

use of the ground water in the basin. Further, in conventional water balance studies it may not be possible to consider, the aerial variability and distribution of the surface and ground water available and its use in the basin, with respect to the locations of the various reservoirs and water use points. Therefore, an optimization model based on linear programming was applied, which incorporates the above aspects of planning effectively.

The main objectives of this study are as follows: (i) To evaluate the utilizable surface and ground water resources on monthly basis for all 16 sub-basins and Cauvery river basin as a whole, (ii) To estimate the water demands for the year 2050 AD for different uses and to make the water balance studies on monthly basis for all the 16 sub-basins and the Cauvery basin as a whole, (iii) To develop a linear programming optimization model for a river basin, planning and development for conjunctive water use, with the aim to maximize the water utilization including intra-basin water transfers, and to determine optimal and sustainable cropping pattern in terms of irrigation intensity and productivity per unit of water, and apply it to the Cauvery river, (iv) To study and analyze in detail the interim award given by the CWDT for sharing of the Cauvery waters by the co-basin states in respect of the present study objective at SI. No. (iii), and (v) To draw suitable conclusions from the above study.

It is found that during normal and bad water years, the Middle Cauvery sub-basin is the only water surplus sub-basin, where as the Noyil and Arkavathi sub-basins suffer the most from water deficit and the Chinnar sub-basin the least. The Kabini sub-basin is not able to fulfill its intra-basin requirements completely during normal and bad water years. From Mettur reservoir, a maximum of 7200 MCM can be exported (as intra-basin export) to the sub-basins below Mettur during a normal water year. During a

normal water year, the water share ratios above and below Mettur for 5800 MCM exports (as intra-basin export) from Mettur reservoir to the sub-basins below Mettur is 0.98. The intra-basin water importing needs from outside the Cauvery basin, during normal water year may be about 13444 MCM. From the linear programming results, during a normal water year, the water extensive crops would not completely acquire their respective crop areas at six reservoirs. The high benefit crops would acquire very little crop areas at two reservoirs. Two reservoirs would require import of Sugarcane. Upper Nugu reservoir is the most affected reservoir in terms of the crop area occupation. Out of sixteen sub-basins nine sub-basins would spill in all the months during a normal water year. Generally, a maximum monthly water utilization factor of I would be achieved in different months at all the sub-basins, except two sub-basins. Similarly, a minimum of about 0.25 monthly water utilization factors would be achieved, with and without ground water considerations. From the LP model result, the maximum annual water utilization factor of 1 at Chinnar sub-basin and the minimum annual water utilization factor 0.19 at Noyil sub-basin would be achieved.

Salary.

## **ACKNOWLEDGEMENTS**

I wish to record my sincere thanks with profound sense of respect and gratitude to Prof. D. K. Srivatsava, Department of Hydrology, I.I.T. Roorkee, Roorkee and Prof. Nayan Sharma, WRDTC, I.I.T. Roorkee, Roorkee, for their valuable guidance, constant encouragement alert supervision and whole hearted cooperation throughout the preparation of this research work.

I am thankful to Dr. Bharat Singh, Professor Emeritus, Water Resources Development Training Centre (WRDTC) and former Vice Chancellor, University of Roorkee, Now Indian Institute of Technology, Roorkee, (India), for suggestion of the topic and help for collection of data from National Water Development Agency, New Delhi.

I also express my gratitude to Prof. S. K. Tripathi, who has guided me in getting permission for Ph.D. from Irrigation Department, Government of Maharashtra and to come to I.I.T. Roorkee for research work, after completion of my M.E. (IWM) from WRDTC, University of Roorkee, Roorkee, in July 1992- December 1993.

I also express my special gratitude to Prof Devadutta Das, Professor WRDTC, for purchasing and providing me LINDO software from Chicago USA, for running my linear programming model at computer laboratory of WRDTC to complete my research work.

I am also thankful to Prof. U.C. Chaube, Head of the Department, WRDTC, IIT Roorkee, Prof. G.C.Mishra, Prof. Gopal Chauhan, Prof. B.N Asthana, Prof. V. Bhairati, Prof. Rajpal. Singh, Prof. Rampal Singh, Dr. Deepak Khare, Associate Professor, Dr. M.L. Kansal, Associate Professor, WRDTC, for providing me the latest technology whenever required throughout my research work.

I am very much thankful to Dr. Sunita Devi, Programmer, Computer Laboratory, WRDTC, IIT Roorkee, for her constant encouragement and valuable help for running my Linear Programming computer model.

I am thankful to all staff at WRDTC and Department of Hydrology for their cooperation.

I am deeply indebted to the Irrigation Department, General Administration Department and Finance Department; Government of Maharashtra, for permitting me and sanctioning my leave to complete this Ph.D. work.

I am thankful to Er. S.A. Nagre, Chief Engineer, Irrigation Department, Government of Maharashtra, for guiding me to do my M.E (IWM) course at WRDTC, University of Roorkee, Roorkee, which is further extended my study in this Ph.D. work. I am thankful to Er. V. V. Gaikwad, Chief Engineer, Irrigation Department, Government of Maharashtra who has first sown the seed of Ph.D. in my mind and told me to continue research work after my completion of M.E. (I.W.M) in December 1993 here but which was not possible due to family constraints at that time and now the dream came true.

I am thankful to Er. Sodal, Secretary, Irrigation Department, Government of Maharashtra for sanctioning my study leave. I am thankful to Er. Ekanathrao Patil, Chief Engineer, Er. B.N Kandarphale, Superintending Engineer, Er. A.A.Kapole, Executive Engineer, Irrigation Department, Government of Maharashtra, for their constant departmental help during completion of this research work.

I wish to express my special thanks to Dr. M.P. Rajurkar, for preparation of my paper presentation at International conference at Colorado, USA and constant guidance during the research work and all my research colleagues Dr. S. Bala Prasad, Dr. UP Gupta, Dr. M.G Sharma, Dr. M. Abdullah, Dr. Naresh Aggrawal, Dr. (Mrs.) Shagufta, Dr. Harne, Mr. Joy Gopal Jena, Mr. Panigrahi, Mr. Srivastava, Mr. Bibhas Sharma, Mr. Mohd. Fahimoddin, Mr. S. S. Pusadkar and Trainee officers Mr. N. S. R. K. Reddy, Mr. J. Deva Sundar from National Water Development Agency.

I wish to record my sincere thanks with folded hands, profound sense of respect and gratitude to my father D. N. PATIL for encouragement to this study and to attend the international conference at Colorado, U.S.A. for paper presentation.

Finally. I am very much thankful to my wife Sarla Devi, my daughters, Deepali, Mayuri and Samruddhi Patil for showing their patience and understandings during this research work.

(M. D. PATIL)

# **NOTATIONS**

# (A) Variables with Normal Characters

| Variable                                 | Descriptions                                                                          |
|------------------------------------------|---------------------------------------------------------------------------------------|
| Notation  A <sup>k</sup> <sub>i, j</sub> | Irrigation area of crop k, for site i, in sub-basin j                                 |
| b k , j                                  | Net benefit from crop k, of site i, in sub-basin j                                    |
| CC <sub>i,j</sub>                        | Annual capacity of canal at site i, in sub-basin j                                    |
| C <sub>f</sub>                           | Conversion factor from m cm/month to mw-h                                             |
| Ē <sub>i,j,t</sub>                       | Secondary energy generated at dam in mw-h for site i, in sub-basin j, in time t       |
| E i, j                                   | Annual energy target at site i, in sub-basin j                                        |
| e <sub>i</sub> , <sub>j</sub>            | Turbine and generator efficiency of hydropower plant at site i, in sub-basin j        |
| E i, j, t                                | Total energy generated from hydropower plant at site i, in sub-basin j, in time t     |
| El i, j, t                               | Evaporation losses from site i, in sub-basin j, in time t                             |
| $FC_{i,j}$                               | Cereal food requirements of the people living in the area of site i, in sub-basin j   |
| F <sub>i,j,t</sub>                       | Contribution from upstream sites to the site i, in sub-basin j, in time t             |
| FO <sub>i,j</sub>                        | Oilseed crops requirements of the people living in the area of site i, in sub-basin j |
| Fp i, j                                  | Pulses food requirements of the people living in the area of site i, in sub-basin j   |
| He i, j, t                               | Average storage head at dam, for site i, in sub-basin j, in time t                    |
| H <sub>i</sub> , j                       | Hydro power capacity at site i, in sub-basin j                                        |
| H i, j, t                                | Number of hours in the period t at site i, in sub-basin j                             |
| Ī <sub>i, j, t</sub>                     | Local inflow from the surrounding area at site i, in sub-basin j, in time t           |
| $I_{i,j,t}$                              | Natural catchment inflow of site i, in sub-basin j, in time t                         |

| Variable<br>Notation               | Descriptions                                                                                      |
|------------------------------------|---------------------------------------------------------------------------------------------------|
| Ir,,,t                             | Water that joins the main stream just above the irrigation diversion canal site i, in sub-basin j |
| Ir ;                               | Total annual irrigation target from site i, in sub-basin j                                        |
| Ir <sub>i, j</sub>                 | Total annual ground water irrigation target from site i, in sub-basin j                           |
| Ir <sub>i, j</sub>                 | Total annual surface water irrigation target from site i, in sub-basin j                          |
| Iu f                               | Total annual upstream irrigation water use targets of site i, in sub-basin j                      |
| Iu <sup>r,s</sup>                  | Total annual upstream irrigation water use targets from surface water of site i, in sub-basin j   |
| Iu <sub>i, j</sub> <sup>r, g</sup> | Total annual upstream irrigation water use targets from ground water of site i, in sub-basin j    |
| Iu mj                              | Total annual upstream M & I water use target of site i, in sub-basin j                            |
| Iu m,s                             | Total annual upstream M & I water use target from surface water of site i, in sub-basin j         |
| Iu <sub>i,j</sub> <sup>m.g</sup>   | Total annual upstream M & I water use target from surface water of site i, in sub-basin j         |
| K' <sub>i,j,t</sub>                | Reservoir evaporation coefficient for site i, in sub-basin j, in time t                           |
| K i,j,t                            | % of return flow to river from irrigation from site i, in sub-basin j, in time t                  |
| K ", j, t                          | % of return flow to river from irrigation from site w, in sub-basin j, in time t                  |
| $K_{i,j,t}$                        | % annual irrigation from site i, in sub-basin j, in time t                                        |
| K <sub>w,j,t</sub>                 | Reservoir evaporation from site w, in sub-basin j, in time t                                      |
| N <sub>j</sub>                     | Number of sites, in sub-basin j                                                                   |
| NB                                 | Number of sub-basins                                                                              |
| NCI <sup>i, j</sup>                | Total number of irrigated crops at site i, in sub-basin j                                         |
| $NCI_{i,j}^{C}$                    | Number of cereal crops irrigated by the site i, in sub-basin j                                    |
| NCI <sup>O</sup> <sub>i, j</sub>   | Number of oilseed crops irrigated by the site i, in sub-basin j                                   |

| Variable<br>Notation             | Descriptions                                                                                                        |
|----------------------------------|---------------------------------------------------------------------------------------------------------------------|
| $NCI_{i,j}^{P}$                  | Number of pulses crops irrigated by the site i, in sub-basin j                                                      |
| $OC_{i,j}^m$                     | Annual water supply diversion from sites i, in sub-basin j                                                          |
| OC r <sub>i,j</sub>              | Annual irrigation diversion from site i, in sub-basin j                                                             |
| $Od_{i,j,t}$                     | Total release at site i, in sub-basin j, in time t for irrigation and water supply                                  |
| · Od m                           | Release at site i, in sub-basin j, in time t, for water supply                                                      |
| $\operatorname{Od}_{i,j,t}^{r}$  | Release at site i, in sub-basin j, in time t, for irrigation                                                        |
| OE 4, j <sub>E</sub>             | Export from site i, in sub-basin j, to irrigation area p, upstream of site q, in importing sub-basin $j_{\epsilon}$ |
| Og <sub>i, j</sub>               | Total annual ground water target for irrigation, and municipal and industrial from site i, in sub-basin j           |
| Og <sup>m</sup>                  | Ground water available for municipal and industrial from site i, in sub-basin j, in time t                          |
| $Og_{i,j,t}^{r}$                 | Ground water available for irrigation, from site i, in sub-basin j, in time t                                       |
| Og <sup>r</sup> <sub>i,j</sub>   | Total annual ground water target for irrigation, and municipal and industrial from site i, in sub-basin j           |
| Og us                            | Annual upstream ground water available for site i, in sub-basin j                                                   |
| Og ds                            | Annual downstream ground water available for site i, in sub-basin j                                                 |
| $OI_{i,j,p}^{q,j}$               | Import to irrigation area p, upstream of site i, in sub-basin j, from site q of exporting sub-basin j <sub>E</sub>  |
| O <sub>i,j,t</sub>               | Total release from site i, in sub-basin j, in time t                                                                |
| $O_{i,j,t}^{m}$                  | Mandatory releases to downstream natural channel from site i, in sub-basin j, in time t                             |
| O <sup>m</sup> <sub>w,j, 1</sub> | Mandatory releases to downstream natural channel from site w, in sub-<br>basin j, in time t                         |
| р                                | $p^{th}$ irrigation area contributing regenerated flow to downstream site i                                         |
| $P_{i,j,t}$                      | Precipitation directly upon the site i, in sub-basin j, in time t                                                   |
| S i. j, t-1                      | Initial storage in the site i, in sub-basin j, in time t                                                            |

| Variable                        | Descriptions                                                                                       |
|---------------------------------|----------------------------------------------------------------------------------------------------|
| Notation                        |                                                                                                    |
| S i, j. t                       | Final storage in the site i, in sub-basin j, in time t                                             |
| $Sp_{i,j,t}$                    | Secondary water release (spill) from site i, in sub-basin j, in time t                             |
| S p <sub>w,t</sub>              | Secondary water release (spill) from site w, in time t                                             |
| TA <sub>i.j</sub>               | Total cultivable command area (CCA) irrigation for site i, in sub-basin j                          |
| TE 4. j,                        | Export from site i, in sub-basin j, to site q, of importing sub-basin j <sub>E</sub>               |
| $TI_{i,j}^{q,j_E}$              | Import to site i, in sub-basin j, from site q, of exporting sub-basin ji                           |
| $W_{i,j,t}^k$                   | Total water diversion requirements in depth of crop k, at site i, in sub-basin j, in time t        |
| Ws w,j                          | Total annual water supply target from site w, in sub-basin j                                       |
| Ws i, j                         | Annual water supply diversion from sites w, sub-basin j                                            |
| Wsi,j                           | Annual water requirement for industrial use from sites i, in sub-basin j                           |
| Ws RH                           | Annual water requirement for rural human domestic use from sites i, in sub-basin j                 |
| Ws R                            | Annual water requirement for rural domestic use from sites i, in sub-basin j                       |
| Ws <sub>i,j</sub>               | Annual water requirement for live stock use from sites i, in sub-basin j                           |
| Ws ",j                          | Annual water requirement for urban domestic use from sites i, in sub-basin j                       |
| $X_{i,j}$                       | Number of upstream irrigation areas contributing the regenerated flow to site i, in sub-basin j    |
| $\mathbf{y}_{\mathrm{i,j}}^{k}$ | Yield per quintal per hector area of crop k, from site i, in sub-basin j                           |
| Yd <sub>i,j</sub>               | Dead storage capacity of reservoir/site i, in sub-basin j                                          |
| Ydmin                           | Gross capacity up to the minimum pool level of the reservoir/site i, in subbasin j, in time t      |
| $Y_{i,j}$                       | Gross storage capacity of reservoir/site i, in sub-basin j                                         |
| Ymax <sub>i, j, 1</sub>         | Gross capacity up to the normal pool level of the reservoir/site i, in sub-basin j, in time t      |
| Z i, j                          | Number of upstream reservoirs/sites contributing to the flow of downstream site i, in sub-basin j. |

## (B) Variables with Special Characters

| Variable<br>Notation                        | Descriptions                                                                                                        |
|---------------------------------------------|---------------------------------------------------------------------------------------------------------------------|
| α <sub>i, j, t</sub>                        | Load factor at hydropower site i, in sub-basin j, in time t, for each period t is an indicator of the energy demand |
| α <sub>i, j, t</sub>                        | % of annual upstream water use for irrigation of site i, in sub-basin j, in time t                                  |
| α <sub>i, j, t</sub>                        | % of return flow to river from upstream water use for irrigation of site i, in sub-basin j, in time t               |
| β <sub>i, j, t</sub>                        | % of annual water supply from site i, in sub-basin j, in time t                                                     |
| β", j, t                                    | % of return flow to river from water supply from site i, in sub-basin j, in time t                                  |
| β ", j, t                                   | % of return flow to river from water supply from site w, in sub-basin j, in time t                                  |
| $\beta_{w,j,t}$                             | % of annual water supply (Ws w, j) from site w, in sub-basin j, in time t                                           |
| δ", , , t                                   | % of downstream mandatory release (O <sub>i,t</sub> ) returning to river from site w, in sub-basin j, in time t     |
| δ i, j, t                                   | Energy requirement in percentage at site i, in sub-basin j, in time t                                               |
| $\xi_{i,j,t}$                               | % of annual water use for industrial and urban from site i, in sub-basin j, in time t                               |
| ф <sub>i, j</sub>                           | % of annual ground water for industrial requirement from sites i, in sub-basin j                                    |
| φ 1 s                                       | % of annual surface water for industrial requirement from sites i, in sub-basin j                                   |
| φ <sup>RHg</sup> <sub>i, j</sub>            | % of annual ground water for rural human domestic requirement from site i, in sub-basin j                           |
| $\phi_{i,j}^{RH^s}$                         | % of annual surface water for rural domestic requirement from site i, in sub-basin j                                |
| φ <sup>RL<sup>g</sup></sup> <sub>i, j</sub> | % of annual ground water for live stock requirement from sites i, in sub-basin j                                    |
| $\varphi_{i,j}^{RL^s}$                      | % of annual surface water for live stock requirement from sites i, in sub-basin j                                   |
| $\phi_{i,j}^{U^g}$                          | % of annual ground water for urban domestic water requirement from site i, in sub-basin j                           |
| φ <sup>Us</sup> <sub>i,j</sub>              | % of annual surface water for urban domestic water requirement from site i, in sub-basin j                          |

| Variable                       | Danielia                                                                                    |
|--------------------------------|---------------------------------------------------------------------------------------------|
| Notation                       | Descriptions                                                                                |
| $\lambda_{i,j,t}^{k}$          | Land use coefficient for crop k, for site i, in sub-basin j, in time t                      |
| $\omega_{i,j}^{q,j_E}$         | % of export from site i, in sub-basin j, in time t, to site q, of importing sub-basin $j_E$ |
| $\psi_{i,j,t}^{q,j_{\bar{l}}}$ | % of import to site i, in sub-basin j, in time t, from site q, of exporting sub-basin $j_1$ |

# (C) Subscripts and superscripts

| Variable<br>Notation | Descriptions                                                           |
|----------------------|------------------------------------------------------------------------|

#### INTRODUCTION

#### 1.1 GENERAL

Water resources planning and management is broadly concerned with the accurate assessment, identification and development of different water resources systems. The careful planning for allocation of water resources to different activities has become extremely important to meet the ever increasing demand of water supply, hydropower, irrigation, and environmental purposes etc. It emphasizes the need of planning and development of river basin water resources, which is a complex and difficult task, creates numerous political, social, economical, environmental and engineering problems. Most of these difficulties are due to variable inflows and large number of possible alternatives. Optimum panning of a large-scale river basin as a unit of water resources system is having a high priority in the economic development of the country. This has resulted in an urgent need for accurate and efficient management of the water resources for its conservation and use. System engineering provides systematic methodologies for studying and analyzing various aspects of a system and its response to various parameters by using mathematical models. It assists in decisionmaking process for all pertinent constraints by using optimization techniques. Efficient planning of limited water resources is an important requirement in comprehensive planning of river basin water resources. Hence river basin water resource planning has become an increasingly important concept in comprehensive planning of water resources.

#### 1.2 INDIA'S NATIONAL WATER POLICY 2002

According to the National Water Policy 2002 of India, water resources development and management will have to be a hydrological unit such as drainage basin as a whole or a sub-basin, taking into account surface and ground water for sustainable use incorporating quantity and environmental considerations. All individual developmental projects and proposals should be formulated and considered within the framework of such an overall plan keeping in view the existing agreements/awards for a basin or sub-basin so that the best possible combination of options can be selected and sustained. Water should be made available to water short areas by transfer from other areas including transfers from one river basin to another, based on a national perspective, after taking into account the requirements of the areas/basins. Integrated and coordinated development of surface water and ground water resources and their conjunctive use, should be envisaged right from the project planning stage and should form an integral part of the project implementation. Irrigation intensity should be such as to extent the benefits of irrigation to as large number of farm families as possible, keeping in view the need to maximize production. Irrigation being the largest consumer of fresh water, the aim should be to get optimal productivity per unit of water. In view of the vital importance of water from human and animal life, for maintaining ecological balance and for economic and developmental activities of all kinds, and considering scarcity, the planning and, management of this resources and its optimal and equitable use has become a matter of the utmost urgency.

#### 1.3 STUDY AREA

The Cauvery is an inter state river in south India originating in the state of Karnataka and flowing through the states of Karnataka, Kerala, Tamil Nadu and

Pondicherry having a catchment area of 81,155 Km<sup>2</sup>. The state wise drainage areas of Cauvery river basin are Karnataka 34,273 Km<sup>2</sup> (42.2%); Tamilnadu 43,867 Km<sup>2</sup> (54.1%); Kerala 2,866 Km<sup>2</sup> (3.5)% and Pondicherry 149 Km<sup>2</sup> (0.2)%. This river basin has 16-sub-basins. It has 75% and 50% water year dependable surface water potential of 16,470 MCM and 20,253 MCM, respectively. The total of 3,866 MCM ground water potential is available for future use. The water requirement for the population of human and livestock projected to the year 2050AD for all purposes are estimated as 39516 MCM. There are 15 major reservoirs and 58 medium irrigation projects and a large number of minor irrigation projects in the basin. The total irrigable area is 2605200 Ha.

#### 1.4 IMPORTANCE OF THE STUDY

The utilization of the water resources of the transboundary Cauvery river system is under dispute. The interstate water dispute between Karnataka and Tamilnadu about sharing of water and intra basin water transfers is pending from a long time and sometimes creates a law and order problem in the states. The issue has been referred to The Cauvery Water Disputes Tribunal (CWDT). The Supreme Court of India has given the directives to the Government of India for interlinking of major rivers in the Himalayan and the Peninsular regions to reduce the natural imbalance of water in the country. The purpose of the study is also to find the technological and realistic solution for the problem of Cauvery basin. Optimal utilization of available water resources and conservation of the Cauvery river waters are the vital needs in the present context, to meet the growing needs of the population are the vital needs in the present context. The optimal allocation of surface water and ground water is therefore necessary so as to maximize the annual water utilization for irrigation, domestic, industrial, hydropower

and environmental uses. The interim award of CWDT is to release 5800 MCM (205 TMC ft) of water from Karnataka to Tamilnadu at Mettur, the 13<sup>th</sup> reservoir in the 8<sup>th</sup> sub-basin. It would be interesting to carry out the study in reference to the interim award of Cauvery Water Disputes Tribunal (CWDT).

#### 1.5 THE PROBLEM IDENTIFICATION

The transboundary Cauvery river basin, the last but one at the tail end of the Peninsular river system is short of adequate water resource to meet its present and future demands, and the problem of sharing of waters between the two major basin states, Karnataka and Tamilnadu, involving intra basin water transfers has been the subject of a long-standing dispute. The National Water Development Agency (NWDA), the society under the Ministry of Water Resources, Government of India, and The National Commission for Integrated Water Resources Development (NCIWRD) under Ministry of Water Resources, Government of India have carried the studies on the water balance, i.e., the study comprising of the sub-basins/basin wise assessment of, the water yields, the existing uses, the reasonable requirements of the basin states in the foreseeable future and the determination of the order of surpluses/deficits of Cauvery river basin on an annual basis. The NWDA studies have not considered ground water and the environmental water requirements while NCIWRD has considered 2/3 of the estimated ground water potential and the environmental water requirements. For accurate assessment of the water resources, the water balance studies should be carried out on a monthly basis, considering the environmental requirements and ground water availability. In this study the water balance studies are carried out on a monthly basis, considering the environmental requirements and ground water availability. This study is also directed to develop a methodology to test the spatial variations with respect to

project sites and storage effect on the water balance studies of the system. The approach and appropriate technique will naturally vary from problem to problem as the configuration, state of development of the system and stage of decision making vary over a vast range. (Maass et al., 1962; Hufschmids and Fiering, 1966; Hall and Dracup, 1970; Haimes, 1977; Loucks et al., 1981; Stedinger et al., 1983; Goodman, 1984; Vedula, 1985; Srivastava, 1976; Chaturvedi, 1987; Simonomic, 1992; Srivastava and Patel, 1993; Wurbs, 1993; Boney 1993; Sadeghian, 1995; Kohistanti, 1995; Sunita Devi, 1997; Waikar, 1998; Dahe, 2000; Dahe and Srivastava, 2002; Kamal-Ali Abd Al-Mohseen (2002); Jena, 2004; Deepti Rani, 2004). A large number of the studies on river basin planning for large river systems generally have considered basic problem constraints only. Very few such studies in the Indian context have incorporated the interest of co-basin states in terms of sharing of the river waters with intra basin water transfers and limiting its use under numerous techno-economic and management constraints pertaining to treaties/agreements/tribunal awards.

Keeping the above facts in view this study is directed to develop a methodology using linear programming optimization model to test the functioning of the transboundary Cauvery river basin system.

#### 1.6 THE OBJECTIVES OF THE STUDY

Keeping the above facts in view this study is directed to develop a methodology using linear programming optimization (LP) model to test the functioning of the transboundary Cauvery river basin system, which is an inter state river originating in Karnataka and flowing through the sates of Karnataka, Kerala, Tamilnadu and Pondicherry.

The main objectives of this study are as follows:

- (i) To evaluate the utilizable surface and ground water resources on monthly basis for all 16 sub-basins and Cauvery river basin as a whole,
- (ii) To estimate the water demands for the year 2050 AD for different uses and to make the water balance studies on monthly basis for all the 16 sub-basins and the Cauvery basin as a whole,
- (iii) To develop a linear programming optimization model for a river basin, planning and development for conjunctive water use, with the aim to maximize the water utilization including intra-basin water transfers, and to determine optimal and sustainable cropping pattern in terms of irrigation intensity and productivity per unit of water, and apply it to the Cauvery river,
- (iv) To study and analyze in detail the interim award given by the CWDT for sharing of the Cauvery waters by the co-basin states in respect of the present study objective at Sl. No. (iii), and (v) To draw suitable conclusions from the above study.

#### 1.7 THE METHODOLOGY

The methodology adopted to achieve the objectives is outlined below:

#### 1.7.1 Water Balance Studies

The monthly water balance studies were made to know the surplus and deficits to find out whether the monthly water requirements are met or not and whether the monthly intra-basin water transfers within the Cauvery basin are possible. The monthly and annual water balances for each sub-basin are calculated and the monthly and annual surplus and deficit are worked out.

### 1.7.1.1 Estimation of surface water and ground water potential

The 75% water year dependable surface water yields on monthly basis for each sub-basins are calculated by distributing the annual 75% water year dependable yields in the proportion of actual average monthly inflows/yields observed at the nearest gauge and discharge (G&D) sites within or outside of the sub-basins. The sub-basin wise ground water potential and the existing uses are calculated on the area basis from districtwise ground water statistics, the data collected from the Water Resources of India, a publication of Central Ground Board, under the Ministry of water Resources, Government of India, Faridabad. The same procedure is adopted for 50%, 90% and 100% water year dependable flows.

### 1.7.1.2 Assessment of the water requirements/needs

### Domestic requirements/needs

The rural, urban and livestock population has been computed by projecting the 1981 census human population and 1982/83 census livestock population To 2050 AD by using suitable compound annual growth rates for human and one percent for livestock. The domestic water requirements are calculated considering the per capita water requirements of 70 liters, 200 liters and 50 liters per day respectively. The urban population by 2050 AD is taken 60.70% of the total projected population by 2050 AD. The entire water requirement for the urban population and the 50% of the rural population is proposed to be met from surface water. The entire water requirement for live stock population and 50% of the requirement for the rural population is proposed to be met from ground water resources.

#### Irrigation requirements/needs

The irrigation needs are calculated by keeping the utilization of existing and

ongoing major, medium and minor projects undisturbed while the net and gross crop water requirements for future major medium and minor projects have been worked out by climatological approach. It is considered that at least 30% of the maximum culturable area for each sub-basin should be under irrigation for the year 2050 AD and in case of sub-basins having less than 30% of irrigation area the additional area to be brought under irrigation is computed and 50% of this is proposed to be irrigated from future medium projects and the remaining 50% from future minor projects. The ultimate irrigation needs for the future projects are calculated and are used for the water balance studies.

### Industrial requirements/needs

For the industrial requirements, in the absence of relevant data, it has been assumed to be same order as that of domestic water requirements by 2050 AD.

### Hydropower requirements/needs

The total evaporation losses of all Hydropower projects in the catchment area of each sub-basin are considered, as hydropower needs.

### Environmental requirements/needs

The environmental needs to each month are taken equal to 1% of the inflows of those months.

The intra-basin water transfer quantities are taken from the data collected. The regeneration from irrigation, domestic and industrial is taken 10%, 80%, and 80%, respectively of net utilization. The monthly and annual water balances for each month in each sub-basin are calculated and the monthly and annual surplus and deficits are worked out.

### 1.7.2 The Mathematical Modeling Approach

The following is carried out:

- (i) An optimization model for planning and management is considered suitable for this study in view of the large size of problem to be addressed. In accordance with the reported findings, regarding the modeling approaches, and the nature and scope of the present study, and huge number of variables to be handled the linear programming model is found to be promising.
- (ii) To study the effects of the spatial variations with respect to project sites and reservoir storage on the water balance of the system, a project-by-project analysis, and sub-basin wise analysis are carried out.
- (iii) The optimization model was run for 75%, 50%, 90%, and 100% water year dependable flows by using LINDO software package for solution. Irrigation was considered as lumped. The monthly diversions from reservoirs and ground water are obtained.
- (iv) The cropping pattern is studied for each reservoir. The water availability is taken from step (iii) above. The cropping patterns are analyzed keeping in mind:

  (a) The number of paddy crops to be grown, (b) Reducing the area for water extensive crops and (c) Opting for high revenue crops.
- (v) To see the effect of the water surplus and the water deficit years on the water utilization and on intra basin water transfers, the step (iii) is repeated.
- (vi) The minimum food requirement with respect to calorific value of crops is also studied.
- (vii) The above studies also include the consideration of the interim Cauvery Water

  Dispute Tribunal (CWDTIA) award.

Initially, the LP model has been applied to the existing, ongoing and proposed individual reservoir sites (major projects) in the Cauvery river basin and again the above models were used to study and analyze the combined developmental strategies of the river sub-basins and the Cauvery river system as a whole. The approach and the characteristics of the type of the models used are a methodological framework for optimal water utilization of the Cauvery river basin planning. And this thesis is an attempt to combine the major advances of systems analysis by optimization (LP) models, which can be used for multi-reservoir, multi-purpose and multi-irrigation areas water resources systems.

# 1.8 THE MAIN FINDINGS OF THIS STUDY

The main findings of this study are as follows:

- (1) The water balance study showed that, with ground water availability considerations, the Upper Cauvery, Kabini, Tirumanimuttar and Ponnanai Ar sub-basins become water surplus from water deficits, during normal and good water years,
- All the sixteen sub-basins in the Cauvery river system except Middle Cauvery sub-basin, are found short of water during normal and bad water years as determined from the linear programming model, whereas the Noyil and Arkavathi sub-basins suffer the most from water deficit, and the Chinnar sub-basin the least,
- (3) The Kabini sub-basin is not able to fulfill its intra-basin water exports requirements completely during normal and bad water years, as determined from linear programming model,

- (4) As per the LP model results, it is found that the maximum intra-basin water exports (reservoir releases) possible from the Mettur reservoir to the other sub-basins below Mettur for 75%, 50%, 90% and 100% water year dependable flows are 7200 MCM, 7800 MCM, 6900 MCM and 6700 MCM, respectively, while in the water balance studies of the NWDA the maximum proposed exports from Mettur is shown as 12712 MCM for a normal year,
- (5) As per LP model results for 5800 MCM exports from Mettur reservoir to the sub-basins below Mettur it is found that the water share ratios for above and below Mettur for a normal year, and other water years, i.e., a water surplus year, a water deficit year, and a critical water year are in the ratios of 0.98, 1.07, 0.79, and 0.72, respectively,
- from outside the Cauvery basin during a normal and other water years, i.e., a water surplus year, a water deficit year, and a critical water year are in the ratios of 1.00:93:1.26:1.67, respectively,
- Outside the Cauvery basin, during a normal and other water years, i.e., a water surplus year, water deficit year, and a critical water years are in the ratios of 10.92:1.18:1.40, respectively,
- (8) From the linear programming results, during a normal water year, the water extensive crops would not completely acquire their respective crop areas at six reservoirs. The high benefit crops would acquire very little crop areas at two reservoirs. Two reservoirs would require import of Sugarcane. Upper Nugu reservoir is the most affected reservoir in terms of the crop area occupation. Out

of sixteen sub-basins nine sub-basins would spill in all the months during a normal water year. Generally, a maximum monthly water utilization factor of 1 would be achieved in different months at all the sub-basins, except two sub-basins. Similarly, a minimum of about 0.25 monthly water utilization factors would be achieved, with and without ground water considerations. From the LP model result, the maximum annual water utilization factor of 1 at Chinnar sub-basin and the minimum annual water utilization factor 0.19 at Noyil sub-basin would be achieved.

#### 1.9 CHAPTERWISE PLANNING OF THE THESIS REPORT

With respect to the said objectives, this research work is reported in 9 chapters.

Chapter 1

This chapter is introductory in nature, it emphasizes the need for planning and management of limited water resources together with problem identification and objectives of the study.

Chapter 2

This is related to literature review. This chapter deals with the review of literature on the topics of surface water resources, planning of surface water reservoirs, cropping pattern and conjunctive water use within the framework of multi-purpose, multi-receivers and multi-irrigation areas.

Chapter 3

The characteristics of the Cauvery river system, undertaken for this study and the data required for this purpose are given in Chapter 3. This includes data such as inflow at dams, gauging and discharge measurement, capacities of canals and dams, monthly water requirement and time period for each crop, subbasin wise and projectwise culturable command area (CCA),

project wise irrigation and annual utilization, availability of subbasin wise surface and ground water.

Chapter 4 The water balance studies for all the 16 sub-basins of the Cauvery river are made and the detailed methodology is described in Chapter 4.

Chapter 5 A general linear programming model for a complex river basin for surface and ground water utilization is developed in Chapter 5. The model developed in this chapter can be used for the planning and development of any river basin by changing the specific design constraints. The objective function of the model is to maximize the annual water utilisation from irrigation and water supply; to maximize the area to be irrigated; and to maximize the annual food production for self-sufficiency.

Chapter 6

Certain data has to be computed from the available information.

The same has been done in Chapter 6. It includes the computation of land use coefficients, computations of irrigation and water supply diversion coefficients and computations of flows for different water year dependable flows.

Chapter 7 The results of the LP model developed and applied to Cauvery river system are presented in Chapter 7. This model has 3600 constraints based on continuity equation, total release from the reservoir, state wise annual irrigation, water supply, land use, crop water requirement, hydroelectric energy, and some designs constraints according to CWDTIA. Out of these 3570 constraints are equalities and 30 are, less than or equal to type. The decision variables include crop areas; reservoir storage, release and spill;

monthly diversions for irrigation and water supply; capacities of reservoirs and canals; upstream and downstream total annual irrigation and water supply.

The entire analysis of LP model was carried out using LINDO package.

Chapter 8 The analysis and discussion in respect of the model developed and applied to Cauvery river basin is carried out in Chapter 8.

The model has been analyzed over one year interval with monthly time periods. The various graphs drawn are presented in this chapter.

Chapter 9 The conclusions drawn on the basis of the present study and scope for further work are finally given in Chapter 9.

## LITERATURE REVIEW

#### 2.1 GENERAL

The history of Water Resources Development Planning shows a long series of evolutionary changes in analytical methodologies. Water resources systems are very complex in nature. These serve the basic demands of humanity and face numerous social, political, economical, environmental, and engineering problems. Reservoirs are the most important elements of complex water resources system.

As the water resources and river basin planning has become more complex, corresponding analytical techniques have evolved the wide spread use of systems analysis. For optimal utilization of irrigation potential, selection of a suitable cropping pattern, adoption of intensive farming techniques and application of desirable amount of water at proper timing are very important.

Mathematical modeling provides a way, perhaps the principal way of predicting the future behavior of existing or proposed water resources system. A mathematical model is a set of equations that describes and represents the real life water resources system. Application of the systems approach and use of systems analysis techniques and models to the real life systems have improved our understanding of such systems, and contributed to continuous process of developing the methodologies for improving the system planning, management, and operation. Over the last 50 years, we have witnessed advances in our abilities to model the engineering, economic, ecologic, hydrologic, environmental, and sometimes even the institutional or practical aspects of

large complex multipurpose water resources systems. Evaluating the applications of numerous types of models has taught us how limited our modeling skills remain (Loucks, 1992).

Water resources system analysis has now been generally accepted to provide an efficient way of answering the numerous questions regarding planning of a large-scale real life water resources system for which the conventional methods of analysis will be inadequate. The approach and appropriate technique varies from problem to problem depending up on state of development of the system and range of decision-making (Maass et al., 1962; Hufschmidt and Fiering, 1966; Hall and Dracup, 1970; Srivastava, 1976 and 1987; Haimes, 1977; Loucks et al., 1981; Stendinger et al., 1983; Marino and Mohammadi, 1983; Goodman, 1984; Vedula, 1985; Helweg, 1985; Chaturvedi, 1987; Sadeghian, 1991; Afshar et al., 1991; Chavez-Morales et al., 1992; Simonovic, 1992; Srivastava and Patel, 1992; Wurbs, 1993; Wurbs et al. 1993; Boney, 1993; Sadeghian, 1995; Sunita Devi, 1997; Waikar, 1998; Dahe, 2001; Dahe and Srivastava, 2002; Kamal-Ali Abd Al-Mohseen (2002); Jena, 2004; Deepti Rani, 2004).

Good work started around in 1955 with the system analysis application. A system may be optimized with the objective of getting maximum benefit out of a given volume of water or minimizing water losses through flood run off, evaporation or seepage etc. This helped in the planning and management of complex river basins, operation of single reservoir, single and multiobjective reservoirs, and multi reservoirs with multi objective, and cropping pattern, conjunctive use of surface and ground waters, etc.

For a large water resources system the difficulty in the system analysis is primarily due to large number of possible alternative development strategies, and hence the vast computational effort required establishing an optimal development plan. However, the huge costs involved in the construction and operation of such a large scale system and the great potential for cost reduction through improved system design necessitate a planning programme that will determine such an optimal development strategy. Therefore, in a large and complex system, one of the major challenges is to reduce the large set of alternative configurations that need to be examined in detail to a reasonable number without mistakenly eliminating an attractive option. The most commonly suggested approach has been to screen all alternating configurations with mathematical programming techniques to determine the most attractive alternatives.

A critical review related to the problems of multiple reservoirs planning and management and inter sub-basin (intra-basin) and inter-basin water transfers, available in literature of water resources planning and management have been presented in two parts as follows:

# 2.2 REVIEW OF STUDIES IN SYSTEMS ANALYSIS OF COMPLEX WATER RESOURCES SYSTEM

A river basin water resource planning has become an increasingly important concept in comprehensive planning of a complex water resources system. Comprehensive river basin water resources planning are a complex and difficult task, posing numerous social, economic, environmental, and engineering problems. One of most difficult engineering aspects of such a planning effort is the development of optimum expansion policies for timing, sizing and sequencing of surface water storage and conveyance facilities. For large-scale water resources systems the difficulty of this task is primarily due to a large number of possible alternative development strategies. The term optimization means the achievement of best results and may be interpreted in

different ways depending on the relative importance of the specific objectives.

A most widely used and popular approach for studying water resources planning problem is based upon mathematical programming or optimization techniques. The advent of high-speed, high-capacity personal computers and the growing requirement of the society for the optimal use of available water resources have further increased the importance of this subject. Although optimization concept has been used during last four decades, the introduction of modern computing facilities and availability of interacting software has greatly accelerated the solution of optimization problems of complex river basin planning.

This approach consists of solving a set of mathematical equations using digital computers to get an optimal solution. Different types of programming problems have been formulated and solved for carrying out the planning and management of water resources river basin planning. A brief description of the reported research works on water resources systems analysis is presented here.

Maass et al. (1962) reported the results of research on system design conducted over several years by Harvard Water program of the Graduate School of Public Administration. This comprehensive treatment emphasizes the systematic research on the methodology of systems design.

Hall et al. (1968) used deterministic dynamic programming for reservoir operation. Their loss function depends on state as well as control variables. It presented in detail, the operational analysis of a component reservoir-river system and procedure to be used to combine optimally a number of such system into a coordinated, mutually reinforcing, and multiple river system.

Stephenson (1970) illustrates the optimum design of multi-interlinked river

basins using linear programming and the principle of decomposition of linear programming.

Bargur (1972) presented a multisector planning and management approach to water resources that is based on a general equilibrium analysis employing input-output model and linear programming techniques.

Nayak and Arora (1973) considered a chance-constrained formulation of a multireservoir system. Some of the other applications in multi-reservoir analytic models are Simonovic and Marino (1982), Marino and Loaiciga (1985a, 1985b), Pereira and Pinto (1985), Gunaa et al. (1990) and Benedito et al. (1991).

A study (Srivastava, 1976; and Chaturvedi and Srivastava, 1981) dealt with the first stage preliminary screening design model in the context of a sequential system analysis iterative modeling of a complex water resources system. The models were developed in the context of river Narmada, a large river basin in India. Two types of analytical optimization models were used to find a reasonably small set of possible optimal design alternatives. These were linear programming deterministic continuous (LPDC) model and linear programming deterministic discontinuous (LPDD) model. The simulation continued screening on the basis of the information obtained from linear programming model. The LPDC model results may be assumed to be nearly optimum in terms of the objective function and could serve as an input for further screening by simulation. The LPDC model was helpful in selecting the ranges of variables for simulation by random sampling.

Decomposing the problem into simulation and optimization components derives a compact, non-linear optimization formulation for selecting among and sizing potential reservoirs. Reservoir storage capacities needed are determined using a modified sequent peak algorithm to simulate monthly reservoir operation (Lall and

Miller, 1988). Simulation is also employed to determine optimal sizes for hydropower generators at each site.

A simulation model in conjunction with an optimization model was developed for water-development planning and policy-issue analysis on Platte River in Nebraska (Razavian et al., 1990). The general model consisted of three components: simulation, screening and optimization. The focus of this paper was on the economic simulation component, which consisted of water-use and economic sub models. The economic simulation model simulated water uses and losses and calculated associated system costs and economic benefits for a large number of alternative water-development options. The out put was used to analyze the physical and economic efficiencies of each alternative, to select preferred alternatives for further analysis, and to generate data for direct input to a subsequent multi-objective optimization model. The technique was found to be a very efficient and cost effective method of evaluating development opportunities for a complex, multipurpose, multi-reservoir river basin.

Grygier and Stendinger (1985) have examined successive LP, optimal control, and LP-DP algorithms to optimize the operation of a single reservoir, two reservoirs in series, and three reservoirs in parallel. The successive linear programming algorithm was found to be easier to implement and appeared to find a global optimum. For simple system the optimal control algorithm is faster but harder to implement. The solutions obtained by LP-DP algorithm were not found optimal.

Vedula and Mohan (1990) developed a real time operational methodology for the Bhadra reservoir in the state of Karnataka (India). The algorithm has three phases of operation. The first phase determines the optimal release policy for a given initial storage and inflow using SDP. Second phase constituted the flow forecasting using ARIMA model and in the last phase a real time simulation model was developed. In the SDP model, the inflows were assumed to follow a discrete Markov process.

Braga et al. (1991) proposed a methodology to identify the parameters in identifying drought, which include onset, termination and severity, from the available historic data on stream flow and rainfall having seasonal pattern. This modified methodology is applied to the stream flow series of the Bhadra river and the mean a real rainfall series for the catchment of the Bhadra reservoir in Karnataka State, India. The droughts identified by the proposed methodology are concurrent with the historically realized droughts, thus providing the viability and applicability of the methodology in the identification of drought conditions.

Loucks (1992) discussed the role of water resources system models in planning. The major challenge facing water resources system planners and managers, the information they need to meet these challenges, and the role analysis in helping to provide this information, have been discussed. He has reviewed some criteria for evaluating the success of any modeling activity designed to help planners and managers to solve real life problems.

Afzal et al. (1992) developed a linear programming model of different quality water by alternative irrigation. The model described provides a methodology of allocating land and water to different crops wherever low rainfall, limited quantity, and different quality waters are the basic parameters governing the irrigation system.

Mohan and Raipure (1992) developed a linear multi-objective programming model and used the constraint technique to derive the optimal releases for various purposes from a system of five reservoirs in India. Trade-off analysis between conflicting objectives of irrigation and hydropower was carried out.

In the study by Karamouz et al. (1992), a multivariate hydrological time-series analysis and a deterministic optimization technique for determining reservoir-operating rules for multiple reservoirs were investigated. This comprised a three-step cyclic procedure that attempts to improve the initial operating rules for the system. The system required two sets of synthetically generated stream flow series to be used in simulation model. The three step cycle begins with an optimization of reservoir operations for a given set of stream flows. The optimal operations from the solution are then analyzed in a regression procedure to obtain a set of operating rules. These rules are evaluated in a simulation model using a different set data. Based on the simulation results bounds are placed on operations and cycle returns to the optimization model. This continues until one of the stopping rules is satisfied.

In the study by Srivastava and Patel (1992), optimization-simulation models were used for the systems analysis of Karjan irrigation project in India. Two types of optimization models, i.e., linear programming and dynamic programming (continuous and discontinuous) were used for preliminary design purposes. The simulation technique was used for further screening. The linear programming model is most suitable for finding reservoir capacity. Dynamic programming (continuous and discontinuous models) are used for further refining the output targets and finding the possible reservoir carryover storages, respectively.

Crawely and Dandy (1993) used the linear programming thehnique for identification of optimum monthly operation policies for the Adelaide headwork's system in Australia. They developed model with the objective function to minimize the pumping costs while ensuring system reliability by maintaining minimum-target levels in the reservoirs.

Loucks (1995) reviewed the needs and opportunities in developing and implementing decision support system (DSS). The focus of the paper is on the process of the successful DSS development and implementation. An approach and some guidelines are outlined for the development of DSSs. The approach emphasizes and requires considerable iterations. The feedback is required throughout the DSS building, testing and evaluation (debugging), and implementation process. The paper concludes by identifying some research needs and opportunities affecting DSS development and its effective use.

Wurbs (1996) presented a computer-based methodology for optimally sizing flood damage reduction system. The decision variables are the size of each structural component of the system, such as storage capacity for reservoirs and flow capacity for channel improvements, and the choice of which non-structural plan to implement in various regions of the floodplain. The decision criteria are to minimize total system cost, which is the sum of the discounted annual cost of implementing and maintaining each measure and the residual expected annual flood damages. A hydrologic and economic simulation model is combined with a search algorithm. The simulation model incorporates procedures for determining the total economic cost for a specified plan. The optimization algorithm iteratively executes the simulation model in an automated search for the optimum plan.

Wurbs (1997) conducted a simulation study of the Brazos river basin and identified issues and concerns that illustrate the practical complexities of administering and modeling a water allocation system. The key considerations involve sharing of limited supplies by numerous water quality constraints, return flows, hydrologic data compilations, and reliability assessment. He states that the issues affecting evaluation of water availability within the Texas water rights system are representative of other

states as well. The study is useful in highlighting the major concerns, issues and constraints, which are to be handled while managing such systems.

Dandy et al. (1997) made a comparison of simulation, network linear programming, full optimization LP model and the LP yield model for estimating the safe yield of the Canberra water supply system consisting of four reservoirs. They pointed out that, although a simulation model will accurately assess the system yield for an assumed set of operating rules, it will not assess the maximum yield that can be achieved by adopting the best possible set of operating rules for the system. The optimization models can be said to use the optimal operating rules for the system in order to obtain the maximum models. They however pointed out that, if the system yield with a specified reliability needs to be determined, there is considerably more difficulty in using the optimization and yield models.

Srinivasan et al. (1999) presented a mixed-integer linear programming model for reservoir performance optimization. They improved the mixed-integer formulation of Moy et al. (1986) for a more complete representation of the resiliency criteria. The improvements achieved with the modified model is demonstrated using the same example as presented with the original model.

Loucks et al. (2000) presented a discussion on sustainable water resources management in an editorial. As defined in the Brundtland Commission's report "Our Common Future (WCED 1987), a development is sustainable if: it meets the needs of the present without compromising the ability of future generations to meet their own needs. Sustainable water resources system are those designed and managed to fully contribute to the objectives of society, now and in future, while maintaining their ecological, environmental, and hydrological integrity (ASCE, 1998). They must be

planned, designed, and managed in such a way that the life-support system at all biological levels remains functional and that the water and related land resources are not irreversibly degraded over time.

Mariam and Srivastava (2000) adopted implicit stochastic Yield model based on linear programming for planning optimal yield of proposed Morand reservoir in Narmada basin in India, and work out optimal allocations of land and water resources, using crop planning model, to develop cropping pattern for annual reservoir yields that can be obtained from the reservoir for different degree of annual project dependability. They opined that the yield model provides a reasonably acceptable estimate of the annual reservoir yield for planning of the project.

Dahe and Srivastava (2000) have demonstrated the use of yield model for assessment of annual yield of Upper Narmada irrigation reservoir with specified reliability and the extent of availability of irrigation supply failure years. Such an assessment can assist the planners to decide upon the irrigation polices regarding the area to be brought under irrigation with sustainable cropping pattern and to reduce the damage due to the likely shortages in supply during failure years.

Dahe and Srivastava (2001) have worked on effect of reliability and extent of supply during failure years on the annual yield of irrigation reservoir. The paper demonstrates adoption of yield model for the analysis of Halon irrigation reservoir. The effect of reliability as well as the extent availability of annual supply during the failure years on the annual yield irrigation project is studied.

Dahe (2001) has made an optimization approach employing the implicit stochastic yield model based on linear programming address issue of assessment and optimal utilization of annual yield for system of reservoirs. Basic yield is extended to develop multiple yield model for multi-reservoir system to achieve the desired annual

reliabilities target. The study carried out for 25 major irrigation reservoirs in Narmada river basin in India for optimal planning of the river basin projects.

Dahe and Srivastava (2002) have further extended the basic yield model and presented a multi-yield model for multi-reservoir system consisting of single purpose and multipurpose reservoirs with an objective to achieve pre-specified reliabilities for irrigation and energy generation and to incorporate an allowable deficit in annual irrigation target. The yield model is applied to a system of eight reservoirs in the upper basin of the Narmada River in India. They have opined that model can act as a better screening tool in planning by providing output that can be very useful in improving the efficiency and accuracy of detailed analysis methods such as simulation.

# 2.3 APPLICATION OF LINEAR PROGRAMMING IN IRRIGATION

Linear programming (LP) is capable of handling complex water resources problem. Where a large number of decision variables and constraints are involved. The constraints may be on social needs, limitation of resources and other physical and technological, environmental requirements propelling in region.

# 2.3.1 Irrigation Planning Using Linear Programming

The linear programming approach has now become regular exercises in different phases of irrigation project in general and the cropping pattern planning in particular. Simple linear programming models can be formulated to handle water resources system related to a single time period. But in reality the irrigation situations are usually much more complex. The fact remains that the supply of irrigation water from a river or a reservoir depends on rainfall and varies during the same period from year to year. The quantity of water required by a crop at a particular time depends on

two factors, namely the moisture available in the soil and the evapotranspiration rate at that time. Again these factors in turn depend on two other factors, firstly the previous irrigation and secondly the prevailing weather conditions which include rainfall, humidity and temperature etc.

Apart from these considerations the quantity of irrigation water and its time of application also influence the crop returns significantly.

Thus an irrigation system actually involves lot of periodic uncertainties.

Therefore attempts have also been made by some researchers to introduce dynamic and stochastic elements in the linear programming models to overcome the drawbacks of simple deterministic models.

The pioneering applications of linear programming were by Heady (1961), Dorfman (1961) and Guise and Flinn (1970) for the river basin planning and development. Windsor and Chow (1972) developed multi crop and multi soil mathematical model to maximize the net returns from crops grown in a season using various methods of irrigation by using LP technique subject to resource availability. Heady and Micol (1975) formulated a LP model of land and water allocations to improve environment and water quality through soil loss controls. Sarkar and Maji (1976) attempted to develop an optimal drainage program and a cropping pattern for an existing canal irrigation system consistent with most efficient use of available resources through linear programming technique under the availability of unlimited and restricted funds, respectively. Matanga and Marino (1979) developed a linear programming model to obtain optimal cropping pattern. The objective was to maximize yield from the crop under constraints of availability of irrigation water and labour. Kumar and Singh (1980) studied the effect of interaction of irrigation and labour on

cropping pattern. The study revealed that labour played a dominating role in decision making process. There are several important case studies of linear programming application in various phases of irrigation. For example Hiramath (1973) applied multiperiod linear programming for temporal and spatial allocation of irrigation water in Krishnarajasagar project of Mysore State, India.

Heady et al. (1973) developed a linear programming model for the optimal land and water allocation to estimate whether there was enough water to meet the food needs of United States of American by the year 2000 AD. Badenhop and Cashloller (1974) employed linear programming technique to choose most profitable crop combination using alternate set of land and water combination in Tungbhadra irrigation project area in India. Singh et al. (1976) formulated a linear programming model for the optimal allocation of land and water for different winter crops in Hissar district. The objective was to maximize the net profit over a given command area and canal discharge.

Agrawal and Agrawal (1982) used linear programming for water budgeting to maximize agricultural production. The study was based on an area under major irrigated winter crops, their yields per hectare, and the total irrigation water actually applied by canals in district Hissar.

# 2.3.2 Conjunctive Use Management Using Linear Programming

The conjunctive use can be defined as the combined and integrated management of surface water and ground water for optimal utilization of available water resources. In other works it is complementary use of surface and ground water resources to provide enhanced and assured water supplies at minimum cost. The concept of conjunctive use of surface and ground waters is simple in that it tries to take advantage of large free evaporation loss and transportation of water from one point to another

based on the head difference at no cost. Thus when excess surface water is available it can be diverted for irrigation purposes which includes recharge of ground water to build up ground water storage so that the same can be utilized in place and time when surface water is in short supply. By maintaining the ground water level at the reasonable depth one can maintain the ecological balance in the region, minimizing the cost of pumping, avail excessive build up of ground water table and minimize the resulting problems of water logging and salinity. Sometimes the shortage of surface water can be made up by mining of ground water temporally; thus this type of conjunctive water supply system offers flexibility in operation and results in water conservation. It increased the total yield reliability of supply and general efficiency of water system. A comprehensive study of the conjunctive water use is given in Todd (1980) and Coe (1990).

Various research workers have extensively used Linear programming (LP) technique. Rogers and Smith (1970) used LP model to arrive at the optimal allocation of ground water and canal water for conjunctive use planning of irrigation. The optimization was constrained by capacities of river, canal wells and drainage and pumping facilities and cropping pattern. The model was deterministic and emphasized on interaction of surface and ground water system.

Lakshminarayana and Rajgopalan (1977) has applied LP model to Buri Doab in Punjab, India. The model determines the extent of allocation of irrigated area to alternative crops and the amount of seasonal water releases from the two sources. Canal and tubewells necessary for seasonal water crop requirements during a one year crop period of operation are determined such that the benefits from the system is maximized. This is a deterministic model in which the response of the ground water was not considered for withdrawals.

Singh and Sirohi (1977) applied linear programming techniques to workout a plan for optimal water distribution among the various crops available from tubewells and upper Ganga Canal in Western UP, India. Sinha and Charyula (1979) developed a linear programming model for the existing irrigation system of Gomati Kalyani Doab, India. Surface water and ground water were planned to be used conjunctively. Various alternative crops were allocated in cultivated areas to determine the optimal cropping pattern.

Yoganarashimhan and Chand (1979) have applied a linear programming model to Gomti Kalayani Doab for maximizing the benefits from irrigation works, subject to a set of constraints. The model select is the cropping pattern from the thirteen crops and gives the allocations of surface and ground waters.

Duggal (1979) suggested an optimization approach for conjunctive use of surface and ground water. Multi period, multi level analysis was carried out by Singh (1981) to optimize land, water, and fertilizer resources for future development.

Both surface and ground water resources were used in LP model for each of the individual river basins and an optimal policy was determined for each of 20 rivers basins and for the country as a whole by Chachadi and Sinha (1988). They have formulated a conjunctive use model based on LP for optimal agricultural production in the sub basin of the Ghataprabha command area in Karanataka State, India. This model has been used to allocate the optimal areas to different crops subject to the water availability constraints from surface and ground water sources.

Vedula (1985) presented a water allocation model for the Upper Cauvery river basin in India. Linear programming is used to determine the reservoir releases, ground water pumping targets, and cropping patterns. The multi objective-planning model maximizes the net benefits and the irrigated areas.

# 2.4 THE HISTORICAL REVIEW OF INTRA-BASIN/INTER-BASIN WATER TRANSFERS

There are large disparities in rainfall and river flows in different parts of India. In this situation, it was natural for engineers and planners to think in terms of water transfer from better endowed to deficient basins. The concept of intra-basin/inter-basin, i.e., inter-linking of Indian rivers is thus not entirely new and was first thought of in the last century. A historical review of existing inter basin links proposals is given below.

# 2.4.1 Lt. Cotton's Comprehensive Navigation Plan

Lt. General Sir Arthur Cotton who was the pioneer of water resources development in India, way back in 1839, stated that water in India is more valuable than gold (Cotton, 1885). He considered that besides irrigation, development of water resources for navigation was of utmost importance as this would contribute to increase of production and economic development through improved transportation (Cotton, 1984 and 1985; Rao, 1975). Lt. Cotton accordingly developed a plan to inter link the rivers in India. The aim was to link Karachi to Calcutta via Kanpur and Cuttak to Bhattkal, Mangalore and Madras. But all that then were able to achieve was series of disconnected water ways, like Midnapure Canal, the Orissa High Level Canal and Kurnool-Cudappah Canal. The venture ended in a failure and had to be taken over by the Government (GOI, 1972).

#### 2.4.2 National Water Grid

Dr. K. L. Rao, one of the most eminent engineers of Independent India, and the Union Minister of Irrigation, proposed a National Water Grid for providing navigation and to remove the spatial disparities in the availability of water in different river basins.

It was based on work done earlier in the Central Water and Power Commission, India. It was noted that the general location of regions of surplus water and deficit is such that trans-basin transfer will be necessary from north and east towards west and south.

Accordingly, Ganga-Cauvery link, off taking near Patna, after it has been joined by its major tributaries Ghagra, Gandak and Sone, passing enroute through the basins of the Sone, Narmada, Tapi, Godavari, Krishna and Pennar, was to connect Ganga and Cauvery as shown in Figure 2.1. Other minor links were also proposed. The 2640 Km long Ganga-Cauvery link essentially envisaged the withdrawal of 1680 cumecs (60,000 cusecs) of flood flows near Patna for about 150 days in a year and pumping about 1400 cumecs (50,000 cusecs) of this water over a head of 449 m for transfer to the peninsular region and utilizing the remaining 2800 cumecs (10,000 cusecs) in the Ganga basin itself. The proposal envisaged utilization of 2.59 million-hectare meters of Ganga waters to bring under irrigation an additional area of 4 million hectares. Dr. Rao had also proposed a few additional links like, (a) Brahmaputra-Ganga link to transfer 1800 to 3000 cumecs with a lift of 12 to 15 m, (b) Link transferring 300 cumecs of Mahanadi waters southwards, (c) Canal from Narmada to Gujrat and Western Rajasthan with lift of 275 m and (d) Links from rivers of Western ghats towards east. The National Water Grid was also considered a network for inland navigation. Dr. Rao had estimated his proposals to cost Rs. 12,500 Crores (NWDA, 1998). A UNDP team was invited to study the proposal and it was endorsed (Rao, 1975). However, that study of the National Water Grid by the Central Water Commission, found that the Ganga-Cauvery link alone will cost about Rs. 70,000 crores at 1995 prices. The annual cost including cost of power would be around Rs. 30,000 per hectare, while the NWDA proposal for inter linking rivers between Ganga and Cauvery at 1996 prices has been

estimated to cost only around Rs. 15, 000 per hectare annually (NWDA, 1998). Then the scheme has not been pursued.

#### 2.4.3 Garland Canal

Captain Dastur, an air pilot, proposed an impressionistic idea to interconnect the rivers of India. His idea was a form of a Garland around the peninsula and a long canal at the foothills of the Himalayas. The two were proposed to be joined by pipes. The Himalayan canal was to be a 4200 km long, 300m wide at constant bed level between 335m and 457m above mean sea level aligned along the southern slopes of the Himalayas running from Ravi in the west to Brahmaputra and beyond in the east. It was visualized to be fed by the Himalayan river waters stored in 50 integrated lakes to be created by cutting the hills slopes of the Himalayas to the same level as the bed of the canal, with another 40 lakes beyond Brahmaputra. The proposal envisaged a storage capacity of 247 BMC to control and distribute 617 BMC of water. The Central and Southern Garland canal was proposed at a constant elevation of between 244m and 305m above the mean sea level, with about 200 lakes having a storage capacity of about 497 BMC to control and distribute 864 BMC of water. The Himalayan and Garland canals were proposed to be inter connected at two points, Delhi and Patna, by five 3.7m diameter pipes to transfer the water (Figure 2.2). Captain Dastur claimed that all the surplus water in the country will be utilized to irrigate 219 million hectares. About 16.8 million volunteers were expected to complete the work in 3 to 4 years. The proposal was estimated to cost of Rs. 24,095 crores at 1974 prices (NWDA, 1998). The proposal was technologically preposterous and should have been summarily rejected. It is, however, being mentioned to bring out the institutional aspects of scientific policy making. The proposals had the full support of the then Prime Minister and apparently

the Ministry could not give sound opinion on its own. Committees were therefore, set up, the proposal was detailed and then estimating that it will cost about Rs.12 million Crores, and the proposal was dropped.

### 2.4.4 National Perspective

The idea to interlink the rivers in India, to overcome the spatial imbalance persisted. The Ministry of Water Resources, Government of India, framed a National Perspective for Water Resources Development in August 1980. It was discussed at various government levels and a National Water Development Agency (NWDA) was set up as an autonomous society to promote scientific development for optimum utilization of water resources of the country and in particular to carry out detailed studies in the context of the National Perspective.

The development, conservation and use of waters thus form one of the main elements in the country's developmental planning to achieve the total production goals in addition to meeting the industrial and other needs of far projected population for 2050 AD (NWDA, 1998).

On this basis it is imperative that it was proposed to link the Brahmaputra and other rivers with national grid to meet the shortages in the various parts of the country (Mohile et al., 1996).

The broad approach adopted in the National Perspective is as follows: (NWDA, 1998).

- (i) Existing uses have been kept undisturbed.
- (ii) Normally water development under the existing legal and constitutional framework is assumed to take place fully by the turn of the century.
- (iii) The development envisaged is within the framework of all the existing agreements among various co-basin states involved.

- (iv) While planning inter-basin and inter-state transfer of water, reasonable needs of the basin states for the foreseeable future have been kept in view and provided for.
- (v) Most efficient use of land and water in the existing irrigation and hydropower station has been kept as a principal objective to be achieved.

## 2.4.5 National Perspective Plan

The National Perspective Plan comprises of two components, namely,

- (i) Himalayan River Development, and
- (ii) Peninsular Rivers Development.

# 2.4.5.1 Himalayan river development

The Himalayan River Component envisage construction of storages on the main Ganga and Brahmaputra rivers and their principal tributaries in India and Nepal so as to conserve monsoon flows for flood control, hydro-power generation and irrigation.

Inter-linking canal systems will be provided to transfer surplus flows of the Kosi, Gandak and Ghagra to the west. In addition, Brahmaputra- Ganga link will be constructed for augmenting dry weather flows of the Ganga (Figure 2.3). Surplus flow available on account of inter-linking of Ganga and Yamuna are proposed to be transferred to the drought prone areas of Haryana, Rajasthan and Gujrat. The scheme will also enable large areas in south Uttar Pradesh and South Bihar to obtain irrigation benefits from the Ganga, with a moderate lift at less than 30m. Further, all land in Tarai area of Nepal would also get irrigation apart from generation of about 30 million KW of hydro-power in Nepal and India. It will also provide flood moderation in the Ganga, Brahmaputra system with this proposal, about 140 BCM of additional water would be

available from these river systems for irrigation on estimated 22 million hectares in the Ganga, Brahmaputra basin apart from Haryana, Punjab, Rajasthan and Gujarat. It would also provide 1120 cumecs (40,000 cusecs) to Calcutta port and would provide navigation facilities across the country. The scheme will benefit not only parts of India but also neighbours Nepal and Bangladesh (NWDA, 1998).

## 2.4.5.2 Peninsular river development

Amongst the Peninsular rivers, the Mahanadi and Godavari are considered to have sizable surpluses after meeting the existing and projected needs of the states within these basins. It is therefore, proposed to provide terminal storages on Mahanadi and Godavari rivers to divert surplus flows of Mahanadi and Godavari system and to further transfer surplus flows of Mahanadi to the Godavari system to water short rivers namely, Krishna, Pennar and Cauvery. The link from Mahanadi to Godavari will be along the east coast and will not involve any lift. The link between Godavari and Krishna will be partly by gravity and partly in the ultimate stage, by lifts of the order of 120m (maximum). The transfer of water would enable irrigation in drought prone areas of Maharashtra, Karnataka, Andhra Pradesh and Tamilnadu by successive exchange. The component is shown in Figure 2.4.

The second component of this proposal is to divert a part of the waters of the west flowing rivers of Kerala to the east for irrigating the drought prone areas of Tamilnadu, apart from bringing new areas under irrigation in Kerala.

The third component is to construct storages and inter-link small rivers, flowing along the west coast, north of Mumbai and south of Tapi. This will enable partial release of waters from Tapi and Narmada which will enable extension of irrigation to Saurashtra and Kutch areas. It will also enable provision of extra water to meet the

growing needs of metropolitan area of Mumbai as well as providing irrigation to the coastal areas in Maharashtra.

The fourth component envisages inter-linking of the southern tributaries of the Yamuna, the Ken and the Chambal in addition to construction of small storages on intermediate tributaries and a dam on the Yamuna at Panchnad. This will enable irrigation in Ujjan and Indore areas of Madhya Pradesh as well as upper areas in Rajasthan.

The proposal of Peninsular River Development will enable additional use of about 84 BCM of water to benefit the States of Orissa, Andhra Pradesh, Maharashtra, Karnataka, Tamilnadu and Madhya Pradesh etc. This will provide additional irrigation benefit of 13 million hectares. The distinctive feature of the National Perspective is that the transfer of water is essentially by gravity and only in small reaches by lift not exceeding 120 m.

# 2.4.6 Examples of Some Intra-basin /Inter-basin Transfers Scheme Implemented in India

The Shenbagavalli Anicut built around two centuries ago in the Sivangiri Zamin in the head reaches of Vaippar basin which is a minor river south of Vaigai. A small weir called the Sherbagavalli anicut was built on a small tributary of Periyar river flowing towards the west. A short canal cutting across the ridge was excavated to divert the water to a tributary of Vaippar river flowing eastwards. This scheme serves 4423 hectare under 40 minor irrigation tanks.

The Periyar project is the most notable endeavour of the last century in transbasin diversion. A masonry gravity dam 47.28 m high has been constructed across a gorge on west flowing Periyar River. A 170 m long tunnel with discharging capacity of 40.75 cumecs has been driven across the mountain barrier to convey the waters eastwards to Vaigai basin. The project was commissioned in 1895 and provided irrigation to 57,923 ha initially which has since been extended to 81,069 ha. Having a power station of 140 MW capacity.

Parambikulam Aliyar project is a complex multi-basin multi-purpose project. Seven streams, five flowing towards the west and two towards the east, have been dammed and their reservoirs inter-linked by tunnels. The water is ultimately delivered to drought prone areas in Coimbatore district of Tamilnadu and the Chittur area of Kerala state. The command area for irrigation is presently 1.62 lakh hectares. There is a total 185 MW power generation capacity at four power houses. This project was built during the second and third five year plans.

Kurnool Cudappa Canal scheme was started by a private company in 1863. A 8.23 m high anicut was built on river Tungbhadra upstream of Kurnool town. A 304 km long canal with a capacity of 84.9 cumecs at its head extends from Krishna to Pennar and irrigates 52.746 ha. The scheme was taken by Government of India in 1982.

The Telgu-Ganga project has been recently implemented primarily to meet the pressing needs of water supply to Chennai metropolitan area. It brings Krishna waters from Srisailam reservoir through an open canal, first to Somasila reservoir in Pennar valley. This involves rock cuts upon 35m deep. From Somasila water is taken through a 45 km canal to Kandaleru and thence to Poondi reservoir in Tamilnadu through another 200km long canal. By mutual agreement 12 TCM or 0.34 BCM of water will be delivered to Tamilnadu at the border from Krishna basin. This will greatly augment the water supply for Chennai city. The canal also irrigates 2.33lakh ha in Andhra Pradesh enroute. The project was made possible by the state of Maharashtra, Karnataka and

Andhra Pradesh voluntarily, foregoing 5TCM each from their entitlement. This project is a fine example of not only of hydraulic engineering but also of inter-state co-operation.

Intra-basin/inter-basin transfers in the Indus basin under the Indus Water Treaty. waters of three eastern rivers, viz. Sutlui, Beas and Ravi were allocated to India. As land to be benefited in India lies mostly to the east and south of these rivers, the rivers had to be inter-linked and waters conveyed to canal systems serving vast tracts in India. The main storage on Sutlaj is at Bhakra, while that on Beas is at Pong. Bhakra system provides irrigation to 26,30,000 ha of new area besides stabilization of existing irrigation on 9 lakh ha. The aggregate generation capacity of Bhakra project is 1354 MW. Direct benefits of Pong include 16 lakh ha irrigation and 360 MW power. A diversion dam at Pandoh, 140 km upstream of Pong on Beas, enables diversion of water from Beas to Bhakra reservoir, and generates 165MW of power on the way. The Beas-Satluj link is 37.25 km long, of which 25.45km is tunnel through difficult rock formations. The capacity of tunnel is 254.7 cumecs. Ranjit Sagar reservoir on Ravi will provide additional water to Beas, and also generate a large block of power. It is no exaggeration to say that the Indus valley water resources development has transformed the entire economy of Punjab, Haryana and Rajasthan. So for as power benefits are concerned, the entire Northern grid shares these.

The projects cited above have been highly benefited and have not resulted in any noticeable environmental damage. The major reservoirs at Bhakra, Pong and Ranjit Sagar dams, did involve considerable rehabilitation problems, which have been largely satisfactorily resolved.

#### 2.4.7 Water Transfers in Other Countries

Many schemes of intra-basin/inter-basin water transfers have been planned, and some of them implemented in other countries.

Sixteen major inter-basin water transfer schemes have been implemented in Canada, mainly for hydropower. In USA the longest and best known schemes implemented so far is California State Water Project.

In United States, The California's State Water Project which diverts 4 cubic km of water from northern California to the drier central and southern parts of the state was completed in 1973. The conveyance system comprises of 869 km California Aqueduct, a complex system of lined and unlined canals, pumping stations, siphons and tunnels involving a lift of 1220m.

The Texas Water Plan envisages redistribution of water in Texas and New Mexico to meet the needs of the year 2020.

The waters of Colorado river which is the international river between USA and Mexico are being supplied outside the basin to the Imperial Valley in the California.

In Canada, the major existing inter-basin transfer projects are Kemano, Churchill, Diversion, Welland Canal, James Bay, Churchill falls and Bayd' Espoir etc. Proposed inter-basin water transfers in Canada are North America Water and Power Alliance (NAWAPA), Canadian Water Magnum Plan, Central North American Water Project (CNAWP), Smith Plan etc. for transfer from Canada to U.S.A.

In Mexico, for the Mexico city water supply, transfer from ground waters from the Lerma basin was completed in 1958. The water plan for the North Western Region (PLHINO) conceived a set of inter basin transfers within the Noroeste region.

In Sri Lanka, the Mahaveli-Ganga project includes several inter basin transfer links.

In USSR the notable scheme executed is the Irtysh Karganda scheme in the Central Kazakhstan.

In China the Lingua canal was completed in 214 BC and Grand Canal was completed in 605 AD. Recently completed project in China is Billuna-Dalian interbasin water supply system. Trans-basin transfer of Luhana river to Tiajian and Tengshan, inter-basin diversion of Guang Long province and inter-basin diversions in Fujian province. Diversion of Quiantang river water, diversion of Yellow river surpluses and south to north transfer projects with the West route, Middle route and East route are other proposed projects in China.

These schemes give us confidence in planning and executing schemes in our country. At the same time lesson have to be learnt from their actual performance, economical and environmental point of view. The decision and implementations of the intra-basin and inter-basin water transfers in India as per the directives given by the Supreme Court of India should be taken for execution taking into consideration of fast growing population for 2050AD.

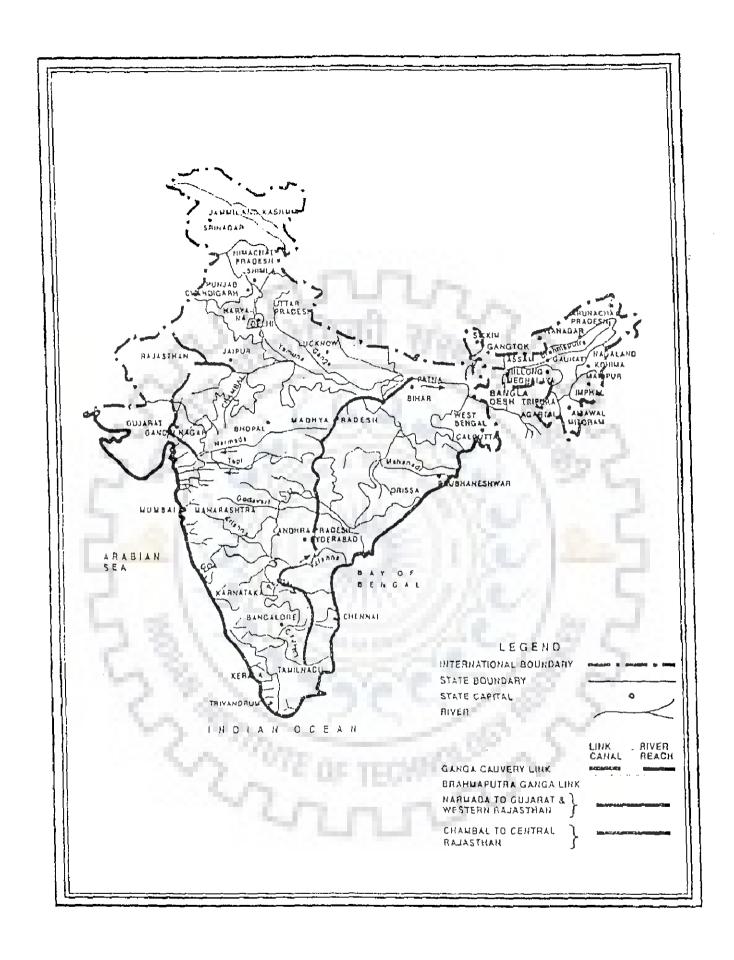

Figure 2.1: Dr. K. L. Rao's Proposal

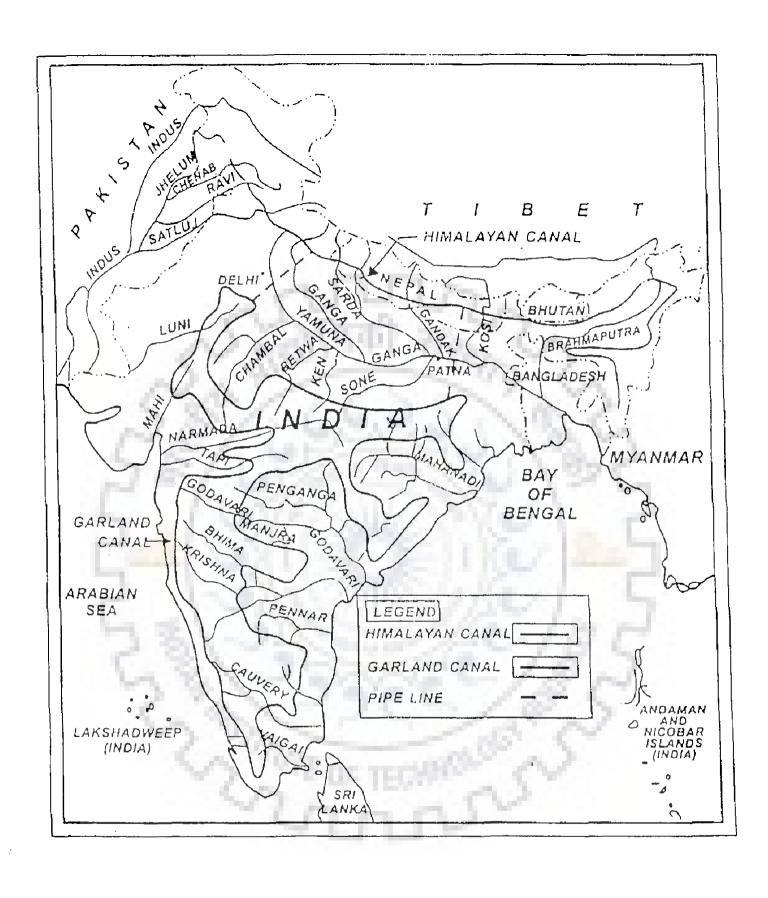

Figure 2.2: Captain Dastur's Proposal

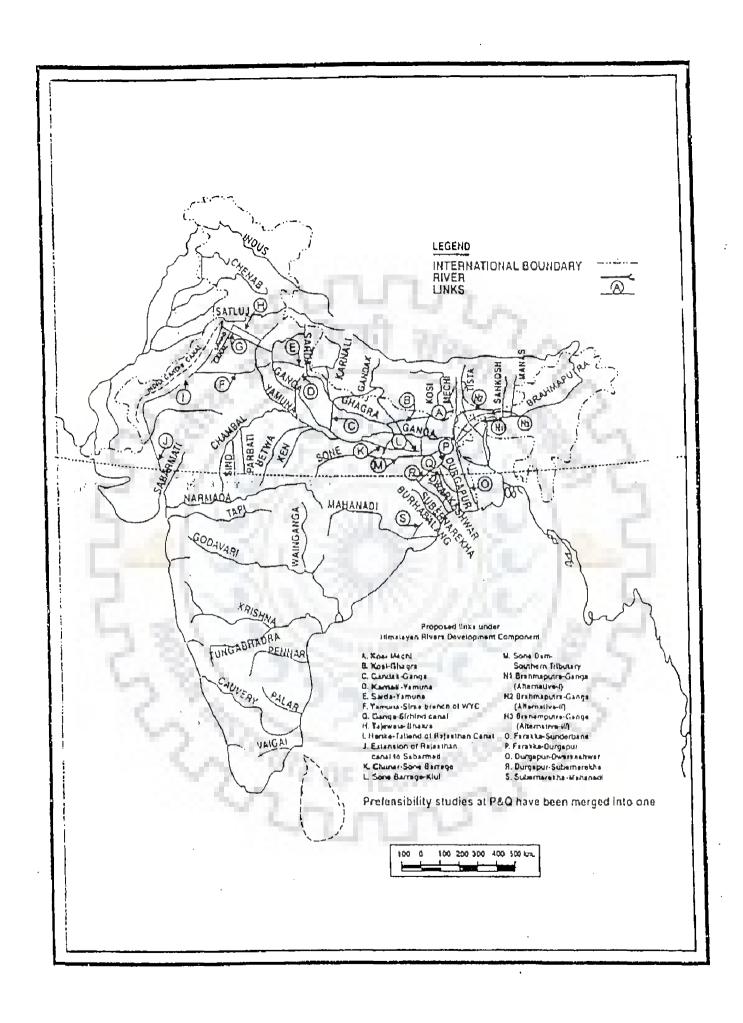

Figure 2.3: Himalayan Rivers Development Component

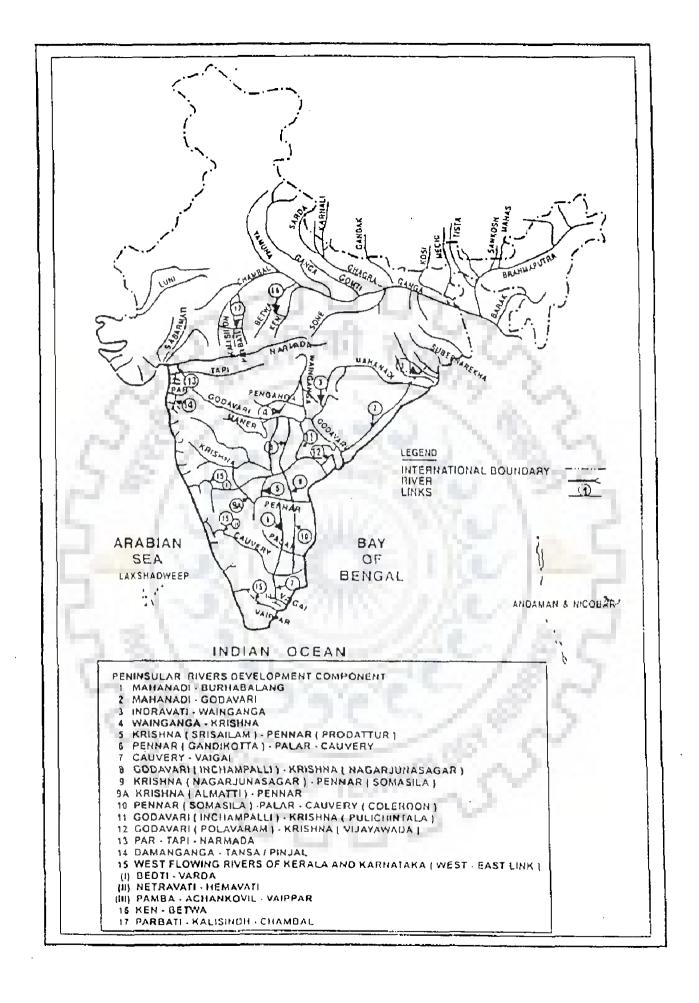

Figure 2.4: The Peninsular Rivers Development Component

# TRANSBOUNDARY CAUVERY RIVER SYSTEM

### 3.1 CAUVERY RIVER BASIN

The Cauvery River is also known as Dakshin Ganga, or 'Ganga of South' in India. The Cauvery is one of the major interstate rivers of South India and is the fourth largest river in the Indian peninsula next only to Godavari, Mahanadi, and Krishna. It rises in the Western Ghats in the Kodagu district of Karnataka at an altitude of about 1341 m above mean sea level (m.s.l) and flows in eastwardly direction passing through the states of Karnataka, Tamilnadu, Kerala and Pondicherry before it drains into Bay of Bengal. The total length of river from source to its out-fall into Bay of Bengal is about 800 km of which 320 km is in Karnataka, 416 km in Tamilnadu and 64 km fall on the common boundaries between Karnataka, Tamilnadu and Pondicherry. The principal tributaries of river Cauvery are the Lakshmanthirtha, Hemavathi, Harangi, Shimsha, Kabini, (which originates in Kerala), Arkavathi, Suvarnavathi in Karnataka, Bhavani (origin in Kerala), Amaravathi (origin in Kerala), Noyil and Ponnanai Ar in Tamilnadu.

The entire Cauvery basin catchment has been divided into 16 sub-basins, viz., (1) The Upper Cauvery (from the source to the Krishnarajsagar dam, i.e., KRS dam, (2) the Kabini, (3) the Shimsha, (4) the Arkavathi, (5) the Middle Cauvery (from the catchment of main river Cauvery from KRS dam at the upstream end to just below the confluence of Arkavathi river with main river Cauvery), (6) the Suvarnavathi, (7) the Palar, (8) the Chinnar, (9) the Bhavani, (10) the Noyil, (12) the Tirumanimuttar, (11) the Amaravathi, (13) the Ponnanai Ar, (14) the Upper Coleroon, (15) the Lower

Coleroon and (16) the Cauvery Delta. The sub-basin wise drainage area, rainfall, runoff and groundwater potential is given in Table 3.1.

Table 3.1: Sub-basinwise Area, Rainfall, Runoff at 75% Water Year Dependable Flow and Ground Water Potential

| Sl. | Name of        | Area              | Rainfall | Runoff* | Ground Water |
|-----|----------------|-------------------|----------|---------|--------------|
| No. | Sub-basin      | (Km <sup>2)</sup> | (mm)     | (MCM)   | (MCM)        |
| (1) | (2)            | (3)               | (4)      | (5)     | (6)          |
| 1   | Upper Cauvery  | 10619             | 1025     | 5394    | 578.5        |
| 2   | Kabini         | 6810              | 1097     | 3641    | 386.4        |
| 3   | Shimsha        | 8469              | 656      | 619     | 506.0        |
| 4   | Arkavathi      | 4351              | 451      | 287     | 103.5        |
| 5   | Middle Cauvery | 2676              | 424      | 330     | 205.6        |
| 6   | Suvarnavathi   | 1787              | 38       | 38      | 63.9         |
| 7   | Palar          | 3214              | 469      | 105     | 139.7        |
| 8 . | Chinnar        | 4061              | 653      | 312     | 177.6        |
| 9   | Bhavani        | 6154              | 908      | 1917    | 187.7        |
| 10  | Noyil          | 2999              | 504      | 225     | 54.2         |
| 11  | Amaravathi     | 8280              | 572      | 898     | 308.0        |
| 12  | Tirumanimuttar | 8429              | 536      | 649     | 350.1        |
| 13  | Ponnanai Ar    | 2050              | 542      | 191     | 207.4        |
| 14  | Upper Coleroon | 3082              | 656      | 589     | 252.6        |
| 15  | Lower Coleroon | 1378              | 815      | 224     | 120.6        |
| 16  | Cauvery Delta  | 6566              | 810.5    | 1051    | 224.6        |

<sup>\* 75%</sup> water year dependable flows.

The Cauvery basin lies between 10° and 13° N latitudes and 75° and 80° E longitudes, bounded by the Western ghats at the west, the Bay of Bengal on the east and the river Krishna, Pennar and the basin area covered by the streams between Palar and Cauvery on the north and the area covered by the streams between Cauvery and

Vaigai on the south.

The catchment area of the Cauvery River is 81155 km<sup>2</sup>, which is nearly 8% of total geographical area of the country. The statewise drainage area of Cauvery basin is given in Table 3.2.

Table 3.2: Statewise Drainage Area of Cauvery Basin

| State       | Drainage Area      | Total Area of the Basin |
|-------------|--------------------|-------------------------|
| State       | (Km <sup>2</sup> ) | (%)                     |
| (1)         | (2)                | (3)                     |
| Karnataka   | 34273              | 42.2                    |
| Kerala      | 2866               | 3.5                     |
| Tamilnadu   | 43867              | 54.1                    |
| Pondicherry | 149                | 0.2                     |
| Total       | 81155              | 100.0                   |

In Karnataka, the basin includes the entire districts of Mysore and Mandya, about three quarters of Hassan district, about two-thirds each of Bangalore and Coorg districts and a part of Tumkur and Chikmagalur districts. In Kerala, the Cauvery basin covers small parts of four districts, i.e., Cannanore, Kozhikode, Iddikki and Palghat. In Tamilnadu, the basin extends over about three-quarters each of the three districts, i.e., Coty, Coimbatore and Tanjavur, about two-thirds of Tiruchirapalli and small parts of Madurai, Salem, Dharmapuri and South Arcot districts.

# 3.2 SUB-BASINS

The basin has been divided into 16 sub-basins for planning purposes by National Water Development Agency (NWDA). Refer various reports in the list of References and Bibliography. The list of sub-basins is shown in Figure 3.1.1 and the tributaries of Cauvery river-basin are shown in Figure 3.1.2 (a) and Figure 3.1.2 (b).

# 3.2.1 Upper Cauvery Sub-basin

The Upper Cauvery Sub-basin lies between latitudes 10<sup>o</sup> 54' and 13<sup>o</sup> 21' N and longitudes 75<sup>o</sup> 30' and 76<sup>o</sup> 36' E comprising the catchment of the Hemavathi, the Laxmanthirtha and the main river Cauvery up to Krishnarajsagar (KRS) dam.

Cauvery rises at Talakaveri on the Brahmagiri ranges in the Western Ghats in the Kodagu district of Karnataka at an elevation of about 1341m above mean sea level. The river flows down from hills in a series of rapids and cascades and is joined at the foot of hills by the Kannike stream at Bhagamandala. The banks are high and steep formed of rich clay. At the border of Kodgu and Mysore districts, the river Harangi joins the Cauvery. The river then flows eastward in the Mysore district where the Hemavathi and the Lakshmanthirtha join on the left bank and right bank, respectively, some distance upstream of the KRS dam. The total length of the Cauvery river in the Upper Cauvery sub-basin up to the Krishnarajsagar dam is about 224 km. The length of the Harangi, Hemavathi and Lakshmanthirtha, all tributaries of Cauvery river in the Upper Cauvery sub-basin is 48 km, 245 km, and 131 km, respectively, from their origin to their confluence with the Cauvery.

The Upper Cauvery sub-basin drains an area of 10619 Km<sup>2</sup> which is about 13% of the total catchment area of the Cauvery basin. The catchment of the Upper Cauvery sub-basin lies wholly in Karnataka covering parts of the Chickmaglur, Kodgu, Hassan, Mandya and Mysore districts. The district wise breakup of the catchment area of the sub-basin is given in Table I.1 in Appendix-I. The irrigation projects in the sub-basin are shown in Figure 3.2.1. The line diagram showing the irrigation projects in the sub-basin is shown in Figure 3.3.1.

### 3.2.2 Kabini Sub-basin

The Kabini river is one of the tributaries of the river Cauvery in its upperreach. The Kabini sub-basin lies between latitudes 11° 29' N and 12° 20' N and longitudes 75<sup>0</sup> 48' E and 75<sup>0</sup> 54' E.

The Kabini river rises in the Western Ghats at an elevation of about 2140 m above mean sea level in the Wyand district of Kerala state. The districtwise breakup of the catchment area of the sub-basin is given in Table I.2 in Appendix-I. The irrigation projects in the sub-basin are shown in Figure 3.2.2. The line diagram showing the irrigation projects in the sub-basin is shown in Figure 3.3.2.

# 3.2.3 Shimsha Sub-basin

The Shimsha sub-basin lies between the latitudes  $12^0$  18' N and  $13^0$  30' N and the longitudes  $76^0$  15' E and  $77^0$  19' E.

The river Shimsha, one of the important tributaries of Cauvery, rises in the south of Devarayanadurga hill in Tumkur district. After flowing southwest in the initial reach, it turns to southwards and then to east. Thereafter pursuing a southerly course, the river enters the Mandya district. Further, it finally takes southeasterly course and joins the Cauvery, a few kilometers below the Shivasmudram falls. The total length of the river Shimsha is about 200 km from its origin to confluence with Cauvery.

The Shimsha sub-basin has a catchment area of 8469 km<sup>2</sup>, which constitutes 10.4 percent of the Cauvery basin area. The entire catchment area of the sub-basin lies in the Karnataka State. The district wise breakup of the catchment area of the sub-basin is given in Table I.3 in Appendix-I. The irrigation projects in the sub-basin are shown in Figure 3.2.3. The line diagram showing the irrigation projects in the sub-basin is shown in Figure 3.3.3.

## 3.2.4 Arkavathi Sub-basin

The Arkavathi sub-basin lies between the latitudes 12

longitudes 77<sup>0</sup> 11' E to 77<sup>0</sup> 42' E.

The river Arkavathi is one of the important tributaries of the river Cauvery. It rises at Nandidurga hills in Chikballpur taluk of Kolar district. After flowing in the southwest direction at the initial stage, it receives along its course, the drainage waters of Kumudvathi river. From this point, the river Arkavathi flows in a southerly direction up to Ramanagaram and turns towards southeast and flows in the same direction up to the confluence of its tributary Suvarnamukhi on the left bank. Thereafter, it flows southerly direction and receives the water of Kuttlehole from the left near Kanakapura town. Further, it flows down and receives the waters of Doddahalla from the left and then finally joins Cauvery at Kungedoddi. The total length of the river Arkavathi is about 150 km from its origin to its confluence with Cauvery.

The Arkavathi sub-basin has a catchment area of 4651 km<sup>2</sup> that constitutes 5.4 percent of the Cauvery basin area. The major portion, i.e., 4184 km<sup>2</sup> (96%) of the catchment area of the sub-basin lies in Karnataka state and the rest 167 km<sup>2</sup> in Tamilnadu (Dharmapuri district). The district wise breakup of the catchment area of the sub-basin is given in Table I.4 in Appendix-I. The irrigation projects in the sub-basin are shown in Figure 3.2.4. The line diagram showing the irrigation projects in the sub-basin is shown in Figure 3.3.4.

# 3.2.5 Middle Cauvery Sub-basin

The Middle Cauvery sub-basin lies between the latitude 11° 52′ N to 12° 48′ N and longitude 76° 30′ E to 77° 29′ E comprising the catchment of main Cauvery from Krishnarajasagar dam to the state boundary just below Mekedatu gorge on river Cauvery.

The river Cauvery below the Krishnarajasagar dam continues to flow

eastwards for 15 km up to Srirangapatnam and then changes its course south-east wards. It receives an important tributary, viz., the Kabini on its right bank at Triumakudal Narasipur and another tributary, viz., the Suvarnavathi joins the Cauvery from the right at Talakad about 25 km downstream. The river then takes a north-east direction and receives the Shimsha from the left, below Sivasmudram. It is here that the river starts cutting through the Eastern Ghats, and from a width of one kilometer, narrows considerably and flows in cascades through a gorge. At Sivasmudram, the river divides into two branches and falls through a height of more than 91 m in a series of falls and rapids. The two major falls are the Ganga Chukki and Bhara Chukki. The fall of river at this point is being utilized for the generation of hydroelectricity power. The Sivasmudram power station built here as early as 1902 is one of the earliest of the hydroelectric power stations set up in Asia. The two branches of the river join after the falls and flow through a gorge, almost too narrow to accommodate the fury of the river. At one point, known as Mekedatu (the goat's leap) the channel is so narrow that it is said that a goat could leap across it. After flowing through a gorge, the Cauvery continues its eastward journey and forms the boundary between Karnataka and Tamilnadu states for a distance of about 64 km. Another left bank tributary, viz., the Arkavathi joins the river just before it enters into Tamilnadu state. The total length of river Cauvery is about 130 km from Krishnarajasagar dam to the state boundary below Mekedatu gorge.

Middle Cauvery sub-basin has catchment area of 2676 km<sup>2</sup>, which constitutes 3.03 % of the Cauvery basin area. The entire catchment area of the sub-basin lies in Karnataka State. The district wise breakup of the catchment area of the sub-basin is given in Table I.5 in Appendix-I. The irrigation projects in the sub-basin are shown in Figure 3.2.5.

## 3.2.6 Suvarnavathi Sub-basin

The Suvarnavathi river is one of the southern tributaries of the Cauvery in its upper reaches. It is the second tributary joining on right bank. The Suvarnavathi subbasin lies between latitudes 11° 35′ N to 12° 10′ N and longitudes 76° 46′ E to 77° 12′E.

The Suvarnavathi river rises in the Nasurghat range of hills situated in the south eastern portion of Mysore district near Gajjala hatti valley and flows northwards through Chamrajasagar and Yelandur taluks. Two streams, viz., Niredurgihalla originating at Attikene estate and Araikaduhalla originating at Dimbum join together near Badibadga to form the river Suvarnavathi or Honhole. This river after flowing for a further distance of 11 km is joined by a tributary, the Chikkahole. After flowing for some more distance about 15 km it is joined by another tributary the Yenehole from left side. The Suvarnavathi river finally joins the Cauvery on its right side at Talakad in the Kollegal taluk. The total length of Suvarnavathi river is about 88 km from its origin to its confluence with the Cauvery. The average bed fall of the river is 6.5 m per kilometer.

The Suvarnavathi sub-basin covers an area of 1787 km<sup>2</sup> in the states of Karnataka and Tamilnadu. It forms 2.2% of the area of the Cauvery basin. The district wise breakup of the catchment area of the sub-basin is given in Table I.6 in Appendix-I. The irrigation projects in the sub-basin are shown in Figure 3.2.6.

### 3.2.7 Palar Sub-basin

The Palar river is one of the southern tributaries of the Cauvery. The Palar sub-basin lies between the latitudes 11° 35' N and 12° 14' N and longitudes 77° 10' E and 77° 50' E.

The Palar rises in the hill ranges of Satyamangalam taluk of Periyar district and flows northwards till it receives a small tributary, namely Moranur Halla from west where river turns perpendicularly to the east and finally joins the Cauvery on right side near the upstream and of Mettur reservoir. The river Palar forms the common boundary between Karnataka and Tamilnadu in Mysore and Periyar districts, respectively, for about 45 km.

The Palar sub-basin comprises, the entire catchments of the Uduthorehalla, the Palar and its tributaries plus the direct catchment of the Cauvery on the right bank, east of the Palar catchment up to Mettur dam. The sub-basin covers an area of 3214 km² in the states of Karnataka and Tamilnadu. It forms 4.0% of the Cauvery basin. The district wise breakup of the catchment area of the sub-basin is given in Table I.7 in Appendix-I. The irrigation projects in the sub-basin are shown in Figure 3.2.7. The line diagram showing the irrigation projects in the sub-basin is shown in Figure 3.3.6.

#### 3.2.8 Chinnar Sub-basin

The Chinnar sub-basin covers the catchment area of the Cauvery basin, on the left bank between the beginning of the common border between Karnataka and Tamilnadu along the Cauvery and Mettur dam, on main Cauvery river. It lies between the latitudes 11° 45' N to 12° 45' N and longitudes 77° 25' E to 78° 20' E. The sub-basin comprises the catchments of four independent streams, namely Chinnar, Doddahalla, Nagavathi and Thoppaiar, the main among them being the Chinnar. The catchment area of the sub-basin as a whole is 4061 km², which constitutes 5% of the total catchment of the Cauvery basin. Most of the sub-basin area lies in Dharmapuri district in Tamilnadu at an elevation ranging from 300 to 900 m. above MSL; only small parts of sub-basin lie in Salem district of Tamilnadu and in Bangalore district of

Karnataka. The district wise breakup of the catchment area of the sub-basin is given in Table I.8 in Appendix-I. The irrigation projects in the sub-basin are shown in Figure 3.2.8. The line diagram showing the irrigation projects in the sub-basin is shown in Figure 3.3.7.

### 3.2.9 Bhavani Sub-basin

The Bhavani river is one of the tributaries of river Cauvery in its mid-reach. The Bhavani sub-basin lies between latitudes 10<sup>o</sup> 56' 3" N and 11<sup>o</sup> 46' 14" N and longitudes 76<sup>o</sup> 24' 41" E and 77<sup>o</sup> 41' 11" E.

The Bhavani river rises at an altitude of about 2634 m in the Billimala range of Nilgiri hills in the Nilgiris district of Tamilnadu. The river flows in the southeast direction up to Makkaliyur and then in the northeast direction up to confluence of the Moyar tributary with the Bhavani. It then runs in the eastward direction up to its confluence with Cauvery.

The length of the river is about 216 km. The Bhavani sub-basin has a catchment area of 6154 km<sup>2</sup>, which constitute 7.58% of the Cauvery basin. The district wise breakup of the catchment area of the sub-basin is given in Table I.9 in Appendix-I. The irrigation projects in the sub-basin are shown in Figure 3.2.9. The line diagram showing the irrigation projects in the sub-basin is shown in Figure 3.3.8.

# 3.2.10 Noyil Sub-basin

This sub-basin comprises the catchment of Noyil river, which includes the catchment of its small tributaries, viz., Sanganurpallam, Vannattangarai, Nallar and Chinnakarai. The Noyil sub-basin lies between latitudes 10° 54' N and 11° 19' N and longitudes 76° 39' E and 77° 56' E. The sub-basin area includes a part of the command

area of Lower Bhavani project canal, Kalingarayan channel and Perimbikulam main canal. The Noyil sub-basin is bounded on the north by Bhavani sub-basin, on the south by Amaravathi sub-basin, on the east by Cauvery river and Western Ghats on the west. The river flows entirely in Tamilnadu and the basin is spread over the districts of Coimbatore, Periyar and Tiruchirapalli. It has a catchment of 2999 km², which constitutes 3.7% of the Cauvery basin. The district wise breakup of the catchment area of the sub-basin is given in Table I.10 in Appendix-I. The irrigation projects in the sub-basin are shown in Figure 3.2.10.

## 3.2.11 Amaravathi Sub-basin

The Amaravathi sub-basin lies between latitudes 10<sup>0</sup> 6' N and 11<sup>0</sup> 2' N and longitudes 77<sup>0</sup> 3' E and 78<sup>0</sup> 6' E and is bounded by Noyil sub-basin in the north, Vaigai basin in south, the southern part of the Western Ghat in the west and the Cauvery river in the east. Except that part of the upper hilly catchment of the sub-basin, which lies in Kerala, the rest of the sub-basin is spread over Tamilnadu.

The river Amaravathi is one among the main tributaries of the river Cauvery in its mid reach. It is the right bank tributary next to Noyil, downstream of Mettur dam in Tamilnadu. Rising from Naimakad at an elevation of 2300 m in the Southern Ghat (Annamalai) in Devikulam taluk of Iddukki district of Kerala State, named as Pampar, flows northeastwards. A number of streams join the river in Kerala before its entry into Tamilnadu. Amaravathi river flows in the same direction in Tamilnadu till its confluence with the river Cauvery on the right bank. Throughout its course of 256 km, the Amaravathi receives a number of small streams. It has a catchment area of 8280 km² which constitutes 10.2% of the Cauvery basin. The district wise breakup of the catchment area of the sub-basin is given in Table I.11 in Appendix-I. The irrigation projects in the sub-basin are shown in Figure 3.2.11.

### 3.2.12 Tirumanimuttar Sub-basin

Tirumanimuttar sub-basin comprises the catchment of Cauvery river below Mettur dam on both sides up to Upper Anicut including the sub-catchment of Sarabhanga Nadi, Tirumanimuttar, Pungar and Ayyar, but excluding the catchments of Bhavani, Noyil and Amaravathi rivers.

The Tirumanimuttar sub-basin lies between latitudes 10° 36' N and 11° 55' N and 77° 27" E and 78° 41' E.

Leaving the Mettur dam, the river Cauvery enters the Tirumanimuttar sub-basin and flows in the southwestern direction along the boundary of Tiruchengode and Bhavani taluka. It receives a small tributary, Chittar river on its right and then the Sarabhanga Nadhi near Kaveripatti on its left. After receiving the Bhavani river on the right at Bhavani opposite to Kumarapalaiyamit, sharply turns south-eastwards and flows along the boundary of the Tiruchengode taluk with the Erode taluk. After Sedarpalaivam bed regulator, it receives the Kurangupallam stream, a small tributary of main Cauvery and then the Novil river on its right. By changing its course in the easterly direction for a short distance, again it continues to flow southeastwards upto the Cattalo bed regulator. In this part of its course, it receives the Tirumanimuttar in Namakkal taluk near Velur on its left and the Amaravathi in Karur taluk on its right. The river then continues to flow in the same direction and leaves this sub-basin at Upper anicut. Below Kattalai head regulator, it receives the Pungar on its right near Kulittalai and the Ayyar river on its left near Upper anicut. Throughout its course of about 185 km length from Mettur to Upper anicut, the river Cauvery receives a number of small streams.

The Tirumanimuttar sub-basin has a catchment area of 8429 Km<sup>2</sup>, which

constitutes 10.39% of the total catchment of Cauvery basin. The sub-basin lies mostly in Salem and Tiruchirapalli districts with only small parts in Periyar and Dindigul Anna districts of Tamilnadu. The district wise breakup of the catchment area of the sub-basin is given in Table I.12 in Appendix-I. The irrigation projects in the sub-basin are shown in Figure 3.2.12.

# 3.1.13 Ponnanai Ar Sub-basin

The Ponnanai Ar sub-basin comprises the catchment of the Ponnanai Ar and its tributary on the right side of the river Cauvery between Upper Anicut and Grand Anicut.

The sub-basin area includes the catchment of the Kodingal Ar which also joins river Cauvery along with the Ponnanai Ar (Kodamuruttri-Ar) upstream of Tiruchirapalli town. The sub-basin also covers a part of the command area of Kattalai canal scheme and New Kattalai high-level canal scheme.

The Ponnanai Ar sub-basin is bounded on the north by Upper Coleroon sub-basin, on the west by Tirumanimuttar sub-basin, on east by Cauvery Delta and on the south by the basin covering the area between the Cauvery and Vaigai river basins. The sub-basin lies between North latitudes 10° 25' 50" and 10° 53' 25" and East longitudes 78° 08' 00" and 78° 50' 00".

The Ponnanai Ar has its origin in the scattered hills near Kadavur in Kulittalai taluk of Tiruchirapalli district and flows in a northeast direction through Kultittala, Manapparai and Tiruchirapalli taluks. It empties into the Cauvery river just above Tiruchirapalli town. Along the course of its travel, it receives the Kuraray River on its right near its confluence with Cauvery. The river Ponnanai Ar is also known as Ariyar in the middle reach and Kodamurutti Ar in the lower reach.

The Ponnanai Ar sub-basin has a catchment area of 2050 km<sup>2</sup>, which constitutes 2.53% of the total catchment area of the Cauvery basin. The sub-basin lies mostly in Tiruchirapalli and Pudukkottai districts with only small parts in Madurai and Thanjavur districts of Tamilnadu. The district wise breakup of the catchment area of the sub-basin is given in Table I.13 in Appendix-I. The irrigation projects in the sub-basin are shown in Figure 3.2.13.

# 3.2.14 Upper Coleroon Sub-basin

The Upper Coleroon sub-basin covers the direct catchment of the Coleroon river, between the Upper Anicut. It lies between the latitudes 10° 50′ N and 11° 15′ N and longitudes 78° 35′ E and 79° 27′ E. The sub-basin also comprises the catchment of a few independent streams such as Upper, Marudaiyar, Nandiyar, Nari Odai, Andi Odai etc. The catchment area of the sub-basin as a whole is 8082 km², which constitutes 3.8% of the total catchment of the Cauvery basin. Most of the sub-basin area lies in Tiruchirapalli district and a small part of sub-basin lies in Thanjavur district of Tamilnadu. The district wise breakup of the catchment area of the sub-basin is given in Table 1.14 in Appendix-I. The irrigation projects in the sub-basin are shown in Figure 3.2.14.

# 3.2.15 Lower Coleroon Sub-basin

The Lower Coleroon sub-basin with a catchment area of 1378 km<sup>2</sup> covers the catchment of the Coleroon river below the lower Coleroon Anicut and extends up to its confluence with the sea. This sub-basin includes the ayacut of the Lower Coleroon Anicut system as well as the catchment of the Veeranam tank situated in the north side of the Coleroon river and its ayacut area. This sub-basin area lies entirely in Tamilnadu

state between latitudes 11° 08' N and 11° 25' and longitudes 79° 13' E and 79° 48' E. The area of this sub-basin constitutes 1.7% of the total catchment of the Cauvery basin. Most of the sub-basin area lies in South Arcot and Tiruchchirappalli districts and a small part of the sub-basin lies in Thanjavur district. The district wise breakup of the catchment area of the sub-basin is given in Table I.15 in Appendix-I. The irrigation projects in the sub-basin are shown in Figure 3.2.15.

# 3.2.16 Cauvery Delta Sub-basin

The Cauvery delta sub-basin comprises the command area of the Vennar branch, Cauvery branch and part of the Grand Anicut canal irrigation system. The sub-basin also covers a part of the command area of Kattalai canal scheme and New Kattalai high-level canal scheme.

Upper Coleroon and Lower Coleroon bound the Cauvery Delta sub-basin on the north, on the west by Tirumanimuttar sub-basin and Ponnanai Ar Sub-basin, on the south by Palk Strait and the basin area covered by the streams between Cauvery and Vaigai and on the east by the Bay of Bengal. The sub-basin lies between North Latitudes 10° 17' and 11° 22' and East Longitudes 78° 48' and 79° 53'.

The Cauvery at Grand Anicut (Upper end of Cauvery Delta sub-basin) subdivides itself into two main branches, viz., Cauvery and Vennar System which get further sub-divided into 36 rivers to feet the delta through a network of main channels and numerous branches, distributaries and sub-distributaries.

The Cauvery delta sub-basin covers a catchment area of 6566 km<sup>2</sup>, which constitutes 8.09% of the total catchment of the Cauvery basin. The sub-basin lies mostly in Thanjavur and Nagappattinam Quaid-E-Millad districts with small parts in Tiruchchirappalli and Pudukkottai districts of Tamilnadu and entire Karaikal area of

Pondicherry state. The district wise breakup of the catchment area of the sub-basin is given in Table I.16 in Appendix-I.

The principal features of the irrigation projects in the Cauvery basin are given in Table 3.3. The irrigation projects in the sub-basin are shown in Figure 3.2.16.

# 3.3 CROPPING PATTERN AND LAND USE COEFFICIENTS

The cropping pattern adopted in the present study, and the cropping pattern used in preliminary water balance studies for the sixteen sub-basins of Cauvery basin is the same as adopted by NWDA. The crop calendar as defined by the time period from preparation and planting the crops up to harvesting the crop was also adopted as per the NWDA reports. The land use coefficients for sixteen sub-basins in Cauvery river basin are computed and presented in Tables 3.4.1(a) to 3.4.16(a).

# 3.4 CROP WATER REQUIREMENT

The crop water requirement is defined as "The depth of water needed to meet the water loss through evapotranspiration of a disease free crop, growing in large field, under non restricting soil conditions including soil water and fertility and achieving full production potential under given growing environment". The assessment of water requirement for various crops is an important factor in choice of crops and one of the basic necessities for crop planning in a command area. The monthwise crop water requirements at reservoir level are obtained from the various reports of NWDA for various sub-basins in Cauvery river basin and are presented in Tables 3.4.1(b) to 3.4.16(b).

# 3.5 CLIMATES, RAINFALL AND STREAM FLOW

The catchment area of Cauvery basin experiences tropical climate. The

maximum and minimum temperatures, observed are 44°C and 18°C respectively. The basin experiences four distinct seasons. They are:

- (i) South west monsoon June to September
- (ii) North east monsoon October to December
- (iii) Cool, dry weather (winter) January to February
- (iv) Hot, dry weather March to May

Maximum rainfall is received along the western border of the basin from the southwest monsoon. Eastern side of the basin gets most of the rain during the northeast monsoon. Depressions in the Bay of Bengal affect the basin in the monsoon causing cyclones and widespread heavy rains. There are 352 raingauge stations in and around the basin. There are 11 Indian Metrological Department (IMD) observatories situated within the basin. The maximum and minimum temperatures, relative humidity, wind velocity, sunshine, and evapotranspiration (Eto) data is computed and published by IMD titled "Potential Evapotranspiration (PE) over India (Scientific report No. 136, 1971) for different IMD observatories. The normal rainfall in the Cauvery basin varies from sub-basin to sub-basin as shown in Table 3.1. The monthly-observed stream flow data in the Cauvery river basin for all the 16 sub-basins are collected from various reports of NWDA, and is presented in Table 3.5.

# 3.6 THE GROUND WATER POTENTIAL

The data required for computation of the sub-basinwise ground water potential available in the Cauvery river basin was collected from Central Ground Water Board Faridabad, under the Ministry of Water Resources, Government of India, from the publication Ground Water Resources of India are (1995). The districtwise ground water resources available in the Cauvery river basin are given in the publication. The ground water potential available in each sub-basin is computed in the proportion of the

districtwise area lying in the sub-basins. The summation of sub-basinwise ground water of all the 16 sub-basin gives the total ground water potential available in the Cauvery river basin.

The sub-basinwise ground water potential is presented in Tables 3.6(a) to 3.6(d).

## 3.7 CAUVERY WATER DISPUTES

The important features of the order of the Cauvery Water Disputes Tribunal are presented below:

The state of Tamilnadu filed a civil miscellaneous petition before Cauvery water disputes Tribunal praying that the state of Karnataka be directed not to impound or utilize water of Cauvery river beyond the extent impounded or used by them as on 31.5.1972, as agreed to by the Chief Ministers of Cauvery basin states and the Union Minister for Irrigation and Power. It further seeks passing of an order restraining the state of Karnataka from undertaking any new projects, dams, reservoirs, canals etc. and/or from proceeding further with the construction of projects, dams, reservoirs, canals etc. in the Cauvery basin. Another C.M.P. was subsequently filed by the state of Tamilnadu as an emergent petition to direct as an emergent measure, the state of Karnataka to release at least 20 T.M.C. of water as a first installment as the Samba crop cannot be maintained without additional supplies from Mettur reservoir.

During the year 1892, an agreement had made between the then Princely state of Mysore and the state of Madras regarding irrigation reservoirs over thirteen major rivers flowing through the then state of Mysore including the Cauvery and its five Tributaries, viz., Hemavathi, Laxman Thirtha, Kabini, Suvarnavathi and Yagachi. Another agreement had been made between the state of Mysore and the state of Madras governments during 1924 under which Mysore government became entitled to construct a dam and a reservoir across and over the river Cauvery at Kanambadi, now

known as Krishnarajasagar, according to the stipulated specifications. Mysore Government was at liberty to carry out future extensions of irrigation in Mysore under the Cauvery and its tributaries to an extent fixed at 1,10,000 acres in addition to the area of irrigation fixed under the Rules and Regulations. The Madras Government was at liberty to construct on the Bhavani, Amaravathi or Noyil rivers in Madras any new storage reservoir. The agreement also provided that the limitations and arrangements shall be open to reconsideration at the expiry of fifty years from the execution of the agreement. Before expiry of the above period, the Central Government constituted a fact-finding committee to collect all the connected data pertaining to Cauvery water and it had submitted its reports. But no final agreement was arrived at between the states regarding the allocation of waters for the respective states.

The Union Territory of Pondicherry sought an interim order from the Tribunal directing the states of Karnataka and Tamilnadu to release the water already agreed to, that is, 9.355 T.M.C. during the months from September to March.

Undisputedly, Cauvery river is an inter-state river. Therefore, the three states of Kerala, Tamilnadu and the Union Territory of Pondicherry being riparian to the said river are entitled to the release of water of Cauvery river in a reasonable and beneficial manner. In the "Law of International Drainage Basins" edited by A.H.Garreston, R.D.Hayton and C.J.Olmstead, at page 63 it has been pointed out that the equality of right does not give a co-riparian the right to an equal division of water. Rather, equality of right is the equal right of each co-riparian state to a division of water on the basis of its economic and social needs, consistent with the corresponding rights of its co-riparian states, and excluding from consideration factors unrelated to such needs.

The Tribunal made it clear that it will not be appropriate to fix the inflow of water into Mettur dam on the basis of the figures at the time of recording of consensus

arrived at the meeting of Chief Ministers of the state of the then Mysore, Tamilnadu and Kerala in the presence of Union Minister of Irrigation and Power, held on 29<sup>th</sup> May 1972 since more than eighteen years had elapsed as on 1990 and various subsequent events also, including construction of additional dams and reservoirs and other irrigation facilities have taken place. Hence, the Tribunal considered it justifiable to fix the annual releases into Mettur dam by making average of the same for a number of normal years in the immediate past. Besides releases from Krishnarajasagar and Kabini dams of Karnataka, some water from the intermediate catchment area also flows down into Mettur dam. But, the Tribunal decided to fix the releases of water by Karnataka by having regard to the realization made over a span or years in the proximate past after excluding abnormally good and abnormally bad years.

Tamilnadu had furnished before Cauvery Tribunal the following figures for the period of ten years, i.e., 1980-81 to 1989-90 of inflow of water into Mettur dam, as given below:

| Year    | Inflow to Mettur (TMC) |
|---------|------------------------|
| 1980-81 | 394.01                 |
| 1981-82 | 403.20                 |
| 1982-83 | 173.20                 |
| 1983-84 | 230.37                 |
| 1984-85 | 284.36                 |
| 1985-86 | 158.28                 |
| 1986-87 | 187.36                 |
| 1987-88 | 103.90                 |
| 1988-89 | 181.37                 |
| 1989-90 | 175.64                 |

In considering the above figures, Cauvery Tribunal decided to exclude the figures for the years, 1980-81 and 1981-82, which were described by parties as abnormally good years. Cauvery Tribunal also excluded from consideration the figures for the years 1985-86, 1987-88, which were classified to be bad years. The average flow of the remaining six years work out at 205.3 TMC, which was rounded of to 205 TMC.

Karaikal region of Union Territory of Pondicherry at the tail end of Cauvery delta suffered because of utter dearth of water. The Union Territory of Pondicherry had claimed before Cauvery Tribunal 9.355 TMC of water towards irrigation and water supply etc. Cauvery Tribunal directed to release 6 TMC of water by Tamilnadu for Union Territory of Pondicherry.

The grievance of Tamilnadu broadly was that not only the total volume of water from Karnataka for flowing down to Mettur dam was becoming less and less, but also the said releases were not being made timely to meet the needs of cultivation of crops, particularly in Cauvery delta of Tamilnadu. Cauvery Tribunal felt it fair to direct that annual releases be made in a regulated manner from week to week basis from June to May.

The State of Kerala had not applied for any interim order. Hence, the order of Cauvery Tribunal is without prejudice to the claims and contentions of the state of Kerala about the equitable distribution and release of water of river Cauvery and its tributaries.

Cauvery Tribunal directed the state of Karnataka to releases water from its reservoirs in Karnataka so as to ensure that 205 TMC of water is available in Tamilnadu's Mettur reservoir in a year from June to May with effect from 1st of July

1991. The Tribunal also directed that the state of Karnataka should regulate the releases of water in the following manner:

| Month | Releases from Mettur (TMC) |
|-------|----------------------------|
| Jun   | 10.16                      |
| Jul   | 42.76                      |
| Aug   | 54.72                      |
| Sep   | 29.36                      |
| Oct   | 30.17                      |
| Nov   | 16.05                      |
| Dec   | 10.37                      |
| Jan   | 2.51                       |
| Feb   | 2.17                       |
| Mar   | 2.40                       |
| Apr   | 2.32                       |
| May . | 2.01                       |
|       | 205.00 £ 5800 MC           |

In respect of a particular month, releases are to be made in four weeks in four equal instalments. If in a particular week, it is not possible to release the required quantum of water, the said deficit shall be made good in the subsequent week. An amount of 6 TMC of water for Karaikal region of the Union Territory of Pondicherry will be delivered by the state of Tamilnadu in a regulated manner.

Cauvery Tribunal also directed the state of Karnataka not to increase its area under irrigation by water of river Cauvery beyond existing 11.2 lakh acres.

The above order of the Tribunal will remain operative till the final adjudication of the dispute, referred to the Tribunal.

#### WATER BALANCE STUDIES OF CAUVERY RIVER BASIN

#### 4.1 GENERAL

In India, rainfall is confined to the monsoon season and is unevenly distributed both in space and time even during the monsoon season. As a result, frequent droughts and floods affect the country's economy. It is necessary to harness the water resources in a most scientific and efficient manner. Cauvery river basin often faces shortage of water resulting in a longstanding dispute between the upper riparian state of Karnataka and lower riparian state of Tamilnadu. Therefore the water balance studies for different sub-basins and the Cauvery basin as a whole are necessary to quantify the requirements in the sub-basins and the basin as a whole. The monthly water balance technique includes, the assessment of the water yield in the sub basin/basin, quantification of existing uses, and reasonable requirements of basin states in the foreseeable future and the determination of order of surplus/deficits. Such a study is attempted here and the procedure is given in this chapter for the "Kabini sub-basin of the Cauvery River basin in India" and the same procedure is adopted for all the 16 sub-basins, and by adding all the 16-sub-basins, the order of surplus/deficit for Cauvery river basin as a whole is determined for 75%, 50%. 90%, and 100% water year dependable flows as given in this chapter.

#### 4.2 WATER BALANCE OF A RIVER BASIN

For overall assessment of the water balance of a river basin, availability of both surface water and ground water is required to be assessed. To establish the

surplus/deficit in a river basin with reasonable reliability, it is necessary to take into consideration, the total availability of water, the present water utilizations and the utilization, which could possibly be made in the foreseeable future.

The following steps are involved in the surface water and ground water balance of a river basin at the specified site:

- (i) Fill in the missing discharge data, if any.
- (ii) Check the consistency of discharge data.
- (iii) Estimate the regeneration from the upstream water utilisation.
- (iv) Then, the virgin flow is given byVirgin flow = observed flow + upstream water utilizations.
- (v) Derive rainfall-runoff relations for the monsoon period on monthly basis and use the relation for finding run-off from the rainfall record.
- (vi) Calculate the non-monsoon run-off as a percent of the monsoon run-off.
- (vii) Calculate the 75% water year dependable flow/yield from the catchment.
- (viii) Estimate ground water availability based on annual replenishment.
- (ix) Calculate the future projections of human and live stock populations for the year; for which, the water resources planning is being done.
- environmental water requirements with the given guidelines as follows, on the basis of guidelines of NWDA, for water balance studies.
  - (a) Irrigation Water requirements

Existing: As per projects reports, designed,

Ongoing: As per projects reports, designed,

Future: (as per norms of NWDA)

Major projects (irrigation intensity 150 %) water depth in m.

Medium projects (irrigation intensity 125 %) water depth in m.

Minor project (irrigation intensity 100 %) water depth in m.

(b) Domestic water requirements

Urban: 200 liters/day/capita

Rural: 70 liters/day/capita,

Live stock: 50 liters/day/capita

(c) Industrial Water Requirements

As the adequate data is not available about the industries, the water needs are calculated on the same basis as those for domestic. Industrial water is supplied from the surface water.

- (d) Hydropower Water Requirements

  The evaporation loss from the reservoirs should be estimated and added to the consumptive uses. Evaporation losses from the reservoirs: (i) Existing and ongoing reservoirs: (as per actual);

  (ii) Proposed: (20% of utilizable water).
- (e) Environmental Water Requirements

  The monthly/annual environmental water requirements in this study are considered as 1% of the monthly/annual surface water inflows/yields in the sub-basin/basin.
- (xi) Determine the import of water from other basins and the export of water to other sub-basins/basins, both with respect to the basin under consideration.
- (xii) Finally the water balance at the specified site is done in the following manner: -

Water balance = [(The 75% water year dependable flow/yield + Ground water availability + Regeneration + Imports) -(Export + Total water needs)].

(iii) The water balance will be determined by the surplus or the deficit in the basin/sub-basins at that specified site.

## 4.3 A SAMPLE WATER BALANCE OF KABINI SUB - BASIN

The Kabini river is one of the tributaries of the river Cauvery in its upper-reach in South India. The Kabini sub-basin lies between north latitudes 11° 29' and 12° 20' and east longitudes 75° 48' and 75° 54'. The Kabini river rises in the Western Ghats at an elevation of about 2140 m above mean sea level in the Wyand district of Kerala state.

#### 4.3.1 Basin Hydrology

#### 4.3.1.1 Surface water availability

The data of 49-rain gauge stations out of the 52 stations, in and around catchment up to the T. Narsipur G&D site has been considered. The catchment of the sub-basin also being the same as that of the T. Narsipur G&D site, the values of weighted average yearly monsoon rainfall of the sub-basin /up to the T.Narsipur G&D site for the period from 1901-02 to 1985-86 have been computed by Thiessen polygon method.

#### 4.3.1.2 Rainfall and runoff data

For computations of the yield, the rainfall and runoff data is required. As per the Kabini sub-basin NWDA report, there are 18 G&D sites and 1 gauge site in the sub-basin, inflow data of 4 reservoirs and 1 Anicut are also available. The discharge data of

T.Narasipur G&D site has been considered for the hydrological studies as it covers the entire catchment of Kabini sub-basin and also better method of observation is followed at this site. The monthly-observed yield data at T.Narasipur G&D site for the period from 1971-72 to 1985-86 having catchment area 7040 km<sup>2</sup> are given in Table 4.1.

## 4.3.1.3 Upstream utilizations

The utilization upstream of above G&D site through the existing projects has been added to the observed yields at the G&D site and the regeneration from the major and medium projects has been deducted to arrive at gross monsoon yields up to the G&D site of each year for the period from 1971-72 to 1985-86.

There are 8 major/medium existing irrigation projects in the catchment upstream of T.Narasipur G&D site. Out of these 8 projects, 5 are storage projects and the remaining 3 are Anicut channels. In the absence of actual utilisation data in respect of 2 anicuts, the utilisation for the same has been computed from the designed area by adopting a delta of 1.6m uniformly for all the years. For the other projects, the utilisation has been arrived at from the inflow and outflow data of the respective projects. The regeneration from the utilizations of above projects has been computed, taking 18% for old projects, i.e., Anicut channels and Nugu reservoir and 10% in respect of all the other projects.

## 4.3.1.4 Computation of surface water yield

Using the gross monsoon yields of the catchment up to T.Narasipur G&D site and the corresponding weighted average monsoon rainfall of each year for the period from 1971-72 to 1985-86 rainfall run-off relationships have been developed by regression analysis considering both the linear and non-linear forms of equations as given below:

Table 4.1: Monthly Observed Yield of Kabini River at T. Narasipur G&D Site

Units: MCM

| Annual Total | (14) | 4249.8  | 3116.8  | 3597.1  | 3294.5  | 4092.1  | 2216.5  | 3198.4  | 4354.9  | 4778.2  | 4986.2  | 4893.8  | 2712.2  | 2869.3  | 3916.7  | 2552.9  |

(a) 
$$Y = ax + b$$

(b) 
$$Y = ax^b$$

where Y is the gross monsoon yield in mm; X is the weighted average monsoon rainfall in mm; and a and b are regression constants.

The linear equation is found to be the best-fit equation based on the least standard error of estimation and it has been assumed to hold good for the entire sub-basin. The monsoon yields for the period 1901-02 to 1985-86 for sub-basin were computed by substituting the weighted average monsoon rainfall values of each year in the best-fit equation. The percentage of gross non-monsoon yield to the gross monsoon yield is found to be 11.32. Considering this percentage the non-monsoon yields of each year is computed and the same is added to the monsoon yields to arrive at the annual yield of the sub-basin for that year. The annual yield series thus generated is arranged in descending order, from which the 75% water year dependable yield of the sub-basin are found to be 3641 MCM.

# 4.3.1.5 Ground water availability / assessment

From the gross ground water potential, provision for domestic uses and existing irrigation (uses) draft in the sub basin have been assessed on proportionate area basis from district-wise ground water statistics published by Central Ground Water Board (CGWB), under the Ministry of Water Resources, Government of India, report for 1995. Based on these details, total as well as balance ground water available for irrigation development has been worked out. The urban water requirement in full and 50% of the rural water requirement is proposed to be met from groundwater sources and the entire livestock water requirement is proposed to be met from groundwater

groundwater, and for Kabini sub-basin this works out to 225 MCM and 280 MCM for without ground water and with ground water considerations, respectively. The details are given in Tables 3.6(a) to 3.6(d).

### 4.3.2 Compilation of Land Use Statistics

The areas under different land use and their percentage to the geographical area of the sub-basin for five years were compiled from taluka—wise statistics. The cultivable area was taken to comprise net area sown, land under miscellaneous crops and trees, current fallows, other fallows and cultivable waste. The land use figure for the year in which the cultivable area is maximum has been considered in the study.

#### 4.3.3 Imports and Export

#### 4.3.3.1 Imports

There is an existing import of 28.44 MCM of water through Anicut channels from Upper Cauvery sub-basin. Further a quantity of 31.42 MCM of Upper Cauvery water is being used for water supply to Mysore City through right bank low level canal of KRS.

A quantity of 297.33 MCM is envisaged to be imported from Upper Cauvery sub-basin through an ongoing project namely extension under Krishnarajasagar stage-I.

Apart from the above, a small quantity of 2.05 MCM is also proposed to be imported from Upper Cauvery sub-basin through Middle Cauvery sub-basin for Anicut channels under Rabi crops. The total import works out to 359 MCM.

#### **4.3.3.2** Exports

There is no export of water from the existing projects.

As regards ongoing projects, Kabini project stage-I envisages an export of 425.48 MCM and 201.87 MCM to Middle Cauvery and Suvarnavathi sub-basins,

respectively. Other two projects namely Mananthvady multi purpose scheme and Banasursagar Sagar project located in Kerala portion of the sub-basin also envisage an export of 495.50 MCM and 189.00 MCM to Valapattanam and Kuttiyadi basins, respectively, of west flowing rivers of Kerala. The Cauvery water supply scheme stage-III to Bangalore city (Arkavathi sub-basin) which is under construction at present also receives water from Kabini sub-basin to the extent of 98.55 MCM. The export from the proposed Kabini sub-basin project stage-II is estimated to be 95 MCM and 289.63 MCM of water to Middle Cauvery and Suvarnavathi sub-basin, respectively. Thus the total export from Kabini sub-basin is 1795 MCM.

## 4.3.4 Water Requirements / Water Needs

#### 4.3.4.1 General

While planning for water resources development in any basin, an assessment of reasonable needs of the basin in the foreseeable future for various purposes like domestic, irrigation, hydropower and industries is essential. These needs are to be met either from the surface flows or from ground water sources or from a combination of both. Assessment of the reasonable requirements of water in the Kabini sub-basin by the end of 2050 AD under each category has been attempted in the following paragraphs.

The requirement of water for various uses, viz., domestic, irrigation, industrial and hydro-power generation was determined as under.

#### 4.3.4.2 Domestic water needs

The requirement of domestic consumption in the rural and urban areas as well as for the livestock has been obtained by projecting the rural, urban and live stock population of the Kabini sub-basin to the 2050 AD. The requirement of water per capita

per day for rural and urban and live stock populations is considered as 70 liters, 200 liters and 50 liters, respectively.

The population as per census 1981 for states of Karnataka, Kerala and Tamilnadu are available (NWDA Report of Kabini Sub-basin, 1992).

The population and livestock have been projected from 1981 to the year 2050 AD using the formula.

$$P_{2050} = P_{1981} \left[ 1 + \frac{R}{100} \right]^{N}$$

where  $P_{2050}$  = Population in 2050 AD.

 $P_{1981}$  = Population (known) in the year 1981 AD,

R = Compound rate of growth of population, and

N = Number of years.

## 4.3.4.3 Population

For Human population projections, the growth rates assumed are as given in Table 4.2. (Guidelines of NWDA for preparation of preliminary water balance study, 1998):

Table 4.2: Growth Rates for Projecting Human Population

| Period (Years) | Growth rate in % |
|----------------|------------------|
| (1)            | (2)              |
| 1981-1985      | 2.06             |
| 1985-1990      | 2.06             |
| 1990-1995      | 1.93             |
| 1995-2000      | 1.78             |
| 2000-2010      | 1.53             |
| 2010-2020      | 1.10             |
| 2020-2030      | 0.92             |
| 2030-2040      | 0.72             |
| 2040-2050      | 0.48             |

The human population and live stock population for Karnataka, Kerala and Tamilnadu for Kabini sub-basin are as given in Table 4.3.

Table 4.3: Kabini Sub-basin: Projected Human and Livestock Population by 2050 AD

| Population  | Karnataka | Tamilnadu    | Kerala  | Total   |
|-------------|-----------|--------------|---------|---------|
| (1)         | (2)       | (3)          | (4)     | (5)     |
| Urban human | 2770894   | 0            | 0       | 2770894 |
| Rural human | 1041194   | 23027        | 729785  | 1794006 |
| Total human | 3812088   | 23027        | 729785  | 4564900 |
| Livestock   | 711434    | 87 <b>77</b> | 1818490 | 902060  |

The live stock population as per the senses (1982-83) in Kabini sub-basin is projected for 2050 AD as given in Table 4.3. The growth rate for calculating projected live stock population is considered 1% per year. The urban water requirement in full and 50% of the rural water requirement is proposed to be met from surface water resources and this works out to 225.0 MCM. The entire live stock water requirement and 50% of the rural water requirement is proposed to be met from ground water sources and 50% of the domestic water requirement to be met from surface water resources is considered to be available as regeneration.

## 4.3.4.4 Irrigation needs

The modified Penman method was used to compute the crop water requirement.

The annual irrigation under future major, medium and minor schemes is assessed considering irrigation intensity of 150%, 125% and 100%, respectively, as per NWDA norms and the annual utilisation has been determined on climatological approach.

The designed annual irrigation and utilisation in respect of all the existing and ongoing projects have been kept undisturbed in assessing surface water needs. For assessing the surface water needs for irrigation, an estimate has been made of the area that can be brought under irrigation by 2050 AD and the reasonable requirement for irrigating the area. The area that can be brought under irrigation by surface water is taken to comprise the area under irrigation from the existing major, medium and minor projects and the area that would be brought under irrigation from the ongoing and identified future major, medium and minor projects. The water needs for irrigating the crops under future projects including the additional area to be brought under irrigation has been computed on climatological approach. Normal monthly values of potential evapo-transpiration of Mysore observatory computed by modified Penmen's method are given in the IMD publication "Potential Evapo-transpiration (PE) over India" (Scientific Report No. 136, February 1971) and these values are used for computing the net irrigation requirement of different crops.

The potential evapo-transpiration, humidity, temperature, sunshine hours, normal monthly rainfall for Mysore observatory are given in Table 4.4.

The gross irrigation requirement of different crops have been worked out considering an irrigation efficiency of 65% for paddy and 55% for other crops under major and medium projects and an irrigation efficiency of 80% for paddy and 70% for other crops under minor projects. The computations of net and gross irrigation water requirement for different crops are done to find out the irrigation requirements. Considering evaporation losses at 20% of the gross irrigation water requirement for the crops, values of weighted average gross delta have been computed and found to be 1.14 m for major projects, 1.14 m for medium projects and 0.88 m for minor projects. Details of the computation are given in Tables 4.5, 4.6 and 4.7, respectively.

Table 4.4: Metrological Data for Kabini Sub-basin Observed at Mysore I.M.D. Station

| Total        | 100  | n n                | 73.23             |

Add 20% evaporation losses = 14.64

Total water requirement = 87.87

Weighted average delta = 87.87/100

= 0.88 m.

The ultimate annual irrigation water requirements for the existing ongoing and future irrigation schemes are given in the Table 4.8.

Table 4.8: Ultimate Surface Water Requirement for Irrigation

| Category                      | Annu     | al Irrigatio | n (ha) | Annual  | Utilization | (MCM)   |
|-------------------------------|----------|--------------|--------|---------|-------------|---------|
|                               | In basin | From         | Total  | In      | From        | Total   |
|                               | 100      | import       | 70     | basin   | import      |         |
| (1)                           | (2)      | (3)          | (4)    | (5)     | (6)         | (7)     |
| Existing Projects             | 36346    | 1580         | 37926  | 637.77  | 28.44       | 666.21  |
| Ongoing Projects              | 49288    | 41700        | 90988  | 574.63  | 297.33      | 871.96  |
| Identified Future<br>Projects | 92876    | 180          | 93056  | 1033.06 | 2.05        | 1035.11 |
| Total                         | 178510   | 43460        | 221970 | 2245,46 | 327.82      | 2573.28 |

Thus the ultimate annual irrigation water requirement will be 2573 MCM including import of 12 MCM. The climatic data of Mysore IMD station is used for calculating monthly ETo values.

#### 4.3.4.5 Industrial Needs

In the absence of actual data on the existing, ongoing and future industries, the industrial water requirement was assumed to be of the same order as that of ultimate domestic water requirements by 2050 AD. The entire industrial water requirement is proposed to be met from surface water source, which is 280 MCM, and 80% of this requirement is considered to be available as regeneration to the stream. This works out to 224 MCM.

#### 4.3.4.6 Hydropower Needs

There are no existing, ongoing or proposed hydroelectric projects in the subbasin. As such, the requirement of water for hydropower generation is taken as nil.

#### 4.3.4.6.1 Environmental Needs

Environmental needs are considered to maintain the minimum flow required in the river to keep quality of the water to a designed standard which is taken as 1% of the surface water available in the sub basin / basin.

## 4.3.4.7 Regeneration

The quantum of return flows to the stream has been considered as 10% of gross utilization for irrigation from ongoing and future major and medium projects and 18% of the gross water utilized for irrigation from the existing major and medium irrigation projects; and 80% of domestic and industrial needs to be met from surface water resources is considered as regeneration to the stream. The total regeneration works out to 651 MCM.

## 4.3.4.8 Ultimate Surface Water Requirements

The ultimate surface water requirement for irrigation, domestic, hydropower and industrial needs and environmental needs works out to 2577 MCM, 225 MCM, 9 MCM and 280 MCM, respectively. Thus, the total surface waters requirement for all uses in the Kabini sub-basin will be 3127 MCM including 36 MCM for environmental releases.

#### 4.3.5 Water Balance

The water balance taking into account, the water availability, import, export, requirements (water needs) and regeneration is given in Table 4.9 below:

Table 4.9: Water Balance for Kabini Sub-basin

| Sl. I | No. Item       |                                                  | Amount (MCM) |
|-------|----------------|--------------------------------------------------|--------------|
| Ī.    | Surface water  | r availability @ 75% dependability               | 3641         |
| 2.    | Regeneration   |                                                  | 651          |
| 3.    | Surface water  | r import (+)                                     | 359          |

# 4.4 DETAILED SUB-BASINWISE WATER BALANCE STUDY OF CAUVERY

#### 4.4.1 Methodology Used For Water Balance Study

The data required for water balance study, i.e., the total annual irrigation requirements of ongoing, existing and proposed major, medium and minor irrigation projects, exports and imports, rural, urban, livestock population, regenerations from irrigation projects, hydropower use etc. were collected from the various reports of preliminary water balance studies and basic data reports of Cauvery basin from National Water Development Authority, under the Ministry of Water Resources, Government of India, New Delhi.

The following steps were used for computation of water balance on monthly basis for all the sixteen sub-basins in Cauvery basin and Cauvery basin as a whole.

Column 1: Months starting from June to May (i.e. water year).

Column 2: The monthly net irrigation requirements for the proposed major, medium and minor irrigation projects are calculated by climatological approach by using modified Penman method. The gross irrigation requirements were calculated by adding 20 percent to the net irrigation requirements for accounting for the reservoir evaporation losses.

Column 3: The monthly gross irrigation requirements for the existing major, medium and minor irrigation projects are calculated by distributing the annual irrigation requirements of the projects in the same proportion as of the monthly gross irrigation requirements of the proposed irrigation projects.

Column 4: The monthly gross irrigation requirements for the ongoing projects are calculated by distributing the annual irrigation requirements of projects in the same proportion of monthly irrigation requirements of the proposed irrigation projects.

Column 5: The total monthly irrigation requirement of the system is computed by summing the columns 2, 3 and 4.

Column 6: The requirement of domestic consumption in the rural and urban as well as for the livestock has been obtained by projecting the rural, urban and live stock population of a sub-basin/basin to the 2050 AD. The requirement of water per capita per day for rural and urban and live stock population is considered as 70 liters, 200 liters and 50 liters respectively.

Column 7: Due to the non-availability of the data, the monthly and total water requirements of industrial water use are taken equal to the water requirements for domestic purposes.

NWDA. The storage products which are used purely for generation of hydropower as single purpose, the water stored throughout the year for electricity generation and after utilization for electricity generation, the water is released in the parent river. Hence, annual evaporation losses in the single purpose hydropower projects are taken as hydropower requirement and annual hydropower requirement is distributed on the monthly basis in the proportion of the number of days.

Column 9: The monthly environmental water requirements are taken equal to 1 percent of the monthly surface water available in the sub-basin.

Column 10: The monthly water requirement in a sub-basin is computed by summing the water utilizations for irrigation, domestic, industrial, hydropower and environmental purposes.

Column 11: The monthly exports are calculated by distributing the total annual exports in a sub-basin in the proportion of the monthly availability of the surface water in that sub-basin.

Column 12: The monthly gross water requirements are computed by summing all the monthly water requirements for irrigation, domestic, industrial, hydropower, environmental and exports.

Column 13: The monthly imports are computed by distributing of total annual import in the proportion of the monthly irrigation requirements of the importing sub-basin.

Column 14: The monthly regeneration from irrigation water use is assumed as 10 percent to 20 percent of the monthly irrigation water requirements.

Column 15: Regeneration from domestic purposes is computed as 80 percent of the domestic water use.

Column 16: The monthly regeneration from industrial water use is taken as 80 percent of the monthly industrial water use.

Column 17: The total monthly regeneration is computed by summing of monthly regenerations from irrigation, domestic and industrial water uses.

Column 18: The monthly surface water yield in the sub-basin is taken in the proportion of the monthly-observed run-off in the sub-basin.

Column 19: The monthly ground water yield in a basin is computed by distributing the annual ground water yield in the proportion of the monthly irrigation water requirements.

Column 20: The total monthly water availability in a basin is computed summing monthly imports from other basins; monthly regenerations from irrigation, domestic and industrial uses; monthly surface water and ground water yields.

Column 21: The monthly water balance of a basin is the difference between the total monthly water available and the total monthly water utilizations.

If the monthly water availability is more than the monthly utilization in a basin then it is known as water surplus basin; and if the monthly utilization is more than the monthly water availability, then it is known as water deficit basin.

## 4.4.2 Results of Sub-basinwise Water Balance Study

The detailed water balance studies carried out monthly on annual basis for all the 16 sub-basins in the Cauvery river basin for 75%, 50%, 90%, and 100% water year dependable flows, with and without considerations of ground water are presented in the

Tables 4.10.1(a) to Table 4.10.4(h). The abstracts of the sub-basinwise annual water balance studies for Cauvery basin for 75%, 50%, 90% and 100% water year dependable flows, are presented in Table 4.11.1 to Table 4.11.5. The sub-basin wise annual water balance for 75%, 50%, 90% and 100% water year dependable flows without and with ground water are presented in Table 4.12.1 to Table 4.12.4. The sub-basinwise monthly deficits/surpluses for 75%, 50%, 90%, and 100% water year dependable flows, with and without considerations of ground water are presented in the Table 4.13.1 to Table 4.13.4. The sub-basinwise monthly deficits or surpluses in descending order with percent of deficit or surplus for 75%, 50%, 90%, and 100% water year dependable flows, with and without considerations of ground water are presented in the Table 4.14.1 to Table 4.14.16. The graphical presentations of monthly water deficits surplus without groundwater and with groundwater considerations for all the 16 sub-basins are shown in Figures 4.1 to Figure 4.16.

# 4.5 ANALYSIS OF WATER BALANCE STUDIES FOR THE 75% WATER YEAR DEPENDABLE FLOW

The water balance studies are carried out monthly on an annual basis, for with and without considerations of ground water for a normal year, i.e., the 75% water year dependable flow.

4.5.1 The sub-basin wise analysis of the water balance studies for the 75% water year dependable flows, without ground water considerations, for the Cauvery river basin is as follows:

## 4.5.1.1 Upper Cauvery Sub-basin

In the case of water balance studies of Upper Cauvery sub-basin, carried out monthly on an annual basis for the 75% water year dependable flow, without ground

water considerations [refer Table 4.10.1(a)], the sub-basin was found short of water in the months of June and September to April, where as the sub-basin is surplus in its water resources in the months of July, August and May. The maximum deficit of 391.3 MCM (8%) occurred in the sub-basin in the month of October, while the minimum deficit of 17.62 MCM (0.40 %) occurred in the sub-basin in the month of November. The maximum surplus of 598.37 MCM (12%) occurred in the month of July, while the minimum surplus of 18.00 MCM (0.40%) occurred in the month of May. The annual deficit in the sub-basin is 274.4 MCM (6%).

#### 4.5.1.2 Kabini Sub-basin

For the water balance studies carried out monthly on an annual basis for Kabini sub-basin for the 75% water year dependable flow, without ground water considerations [refer Table 4.10.2(a)], it was found that in the sub-basin deficits occurred in the months of September and December to April, while the surpluses occurred in the months of June, July, August, October and May. The maximum deficit of 253.1 MCM (5.2%) occurred in the sub-basin in the month of January, while minimum deficit of 5.67 MCM (0.10 %) occurred in the sub-basin in the month of April. The maximum surplus of 132.86 MCM (2.71%) occurred in the month of June, while the minimum surplus of 4.46 MCM (0.09%) occurred in the month of November. The annual deficit in the sub-basin is 267.8 MCM (5.5%).

#### 4.5.1.3 Shimsha Sub-basin

For the water balance studies carried out monthly on an annual basis for Shimsha sub-basin for the 75% water year dependable flow, without ground water consideration [refer Table 4.10.3(a)], it was found that in the sub-basin deficits

occurred in the months of June to August and December to April, while the surpluses occurred in the months of September to November and May. The maximum deficit of 68.87 MCM (2%) occurred in the sub-basin in the month of January, while minimum deficit of 0.25 MCM (0.02 %) occurred in the sub-basin in the month of June. The maximum surplus of 294.72 MCM (8%) occurred in the month of October, while the minimum surplus of 8.86 MCM (0.2%) occurred in the month of May. The annual deficit in the sub-basin is 150.81 MCM (4%).

#### 4.5.1.4 Arkavathi Sub-basin

In the case of water balance studies of Arkavathi sub-basin, carried out monthly on an annual basis for the 75% water year dependable flow, without ground water considerations [refer Table 4.10.4(a)], the sub-basin was found short of water through out the year. The maximum deficit of 205.2 MCM (10.9%) occurred in the sub-basin in the month of September, while the minimum deficit of 24.56 MCM (1.30 %) occurred in the sub-basin in the month of April. The annual deficit in the sub-basin is 799.2 MCM (42.4%).

# 4.5.1.5 Middle Cauvery Sub-basin

For the water balance studies carried out monthly on an annual basis for Middle Cauvery sub-basin for the 75% water year dependable flow, without ground water consideration [refer Table 4.10.5(a)], it was found that in the sub-basin deficits occurred in the months of January to June, while the surpluses occurred in the months of July to December. The maximum deficit of 3.31 MCM (0.2%) occurred in the sub-basin in the month of March, while minimum deficit of 1.63 MCM (0.01 %) occurred in the sub-basin in the month of January. The maximum surplus of 24.14 MCM (1.1%)

occurred in the month of September, while the minimum surplus of 3.54 MCM (0.20%) occurred in the month of December. The annual surplus in the sub-basin is 67.40 MCM (3.1%).

#### 4.5.1.6 Suvarnavathi Sub-basin

In the case of water balance studies of Suvarnavathi sub-basin, carried out monthly on an annual basis for the 75% water year dependable flow, without ground water considerations [refer Table 4.10.6(a)], the sub-basin was found short of water in the months of June to September and December to May, where as the sub-basin is surplus in its water resources in the months of October and November. The maximum deficit of 17.01 MCM (2.3%) occurred in the sub-basin in the month of July, while the minimum deficit of 0.55 MCM (0.10 %) occurred in the sub-basin in the month of May. The maximum surplus of 6.52 MCM (0.88%) occurred in the month of October, while the minimum surplus of 3.83 MCM (0.52%) occurred in the month of November. The annual deficit in the sub-basin is 80.00 MCM (11%).

#### 4.5.1.7 Palar Sub-basin

For the water balance studies carried out monthly on an annual basis for Palar sub-basin for the 75% water year dependable flow, without ground water consideration [refer Table 4.10.7(a)], it was found that in the sub-basin deficits occurred throughout the year except the months of June and October. The maximum deficit of 30.75 MCM (9.5%) occurred in the sub-basin in the month of July, while minimum deficit of 0.59 MCM (0.20 %) occurred in the sub-basin in the month of May. The maximum surplus of 6.00 MCM (1.9%) occurred in the month of June, while the minimum surplus of 1.84 MCM (0.60%) occurred in the month of October. The annual deficit in the sub-basin is 161 MCM (50%).

#### 4.5.1.8 Chinnar Sub-basin

In the case of water balance studies of Chinnar sub-basin, carried out monthly on an annual basis for the 75% water year dependable flow, without ground water considerations [refer Table 4.10.8(a)], the sub-basin was found short of water throughout the year. The maximum deficit of 4322.6 MCM (32%) occurred in the sub-basin in the month of October, while the minimum deficit of 156.75 MCM (1.20 %) occurred in the sub-basin in the month of July. The annual deficit in the sub-basin is 13103 MCM (96%).

#### 4.5.1.9 Bhavani Sub-basin

In the case of water balance studies of Bhavani sub-basin, carried out monthly on an annual basis for the 75% water year dependable flow, without ground water considerations [refer Table 4.10.9(a)], the sub-basin was found short of water in the months of June to September and January to May, where as the sub-basin is surplus in its water resources in the months of October, November and December. The maximum deficit of 164.53 MCM (5.8%) occurred in the sub-basin in the month of March, while the minimum deficit of 8.84 MCM (0.30 %) occurred in the sub-basin in the month of July. The maximum surplus of 98.8 MCM (3.50%) occurred in the month of November, while the minimum surplus of 35.44 MCM (1.30%) occurred in the month of December. The annual deficit in the sub-basin is 424.90 MCM (15%).

#### 4.5.1.10 Noyil Sub-basin

For the water balance studies carried out monthly on an annual basis for Noyil sub-basin for the 75% water year dependable flow, without ground water considerations [refer Table 4.10.10(a)], it was found that in the sub-basin deficits

occurred in the months of June to September and January to May, while the surpluses occurred in the months of October, November and December. The maximum deficit of 49.75 MCM (4.3%) occurred in the sub-basin in the month of June, while minimum deficit of 11.19 MCM (1.0%) occurred in the sub-basin in the month of September. The maximum surplus of 106.39 MCM (9.2%) occurred in the month of October, while the minimum surplus of 23.26 MCM (2.0%) occurred in the month of December. The annual deficit in the sub-basin is 66.4 MCM (5.7%).

#### 4.5.1.11 Amaravathi Sub-basin

For the water balance studies carried out monthly on an annual basis for Amaravathi sub-basin for the 75% water year dependable flow, without ground water consideration [refer Table 4.10.11(a)], the sub-basin was found short of water in the months of June to September and January to May, where as the sub-basin is surplus in its water resources in the months of October, November and December. The maximum deficit of 207.3 MCM (7.7%) occurred in the sub-basin in the month of March, while minimum deficit of 40.31 MCM (1.50 %) occurred in the sub-basin in the month of September. The maximum surplus of 189.8 MCM (7.1%) occurred in the month of November, while the minimum surplus of 124.3 MCM (4.60%) occurred in the month of October. The annual deficit in the sub-basin is 744.14 MCM (28%).

#### 4.5.1.12 Tirumanimuttar Sub-basin

In the case of water balance studies of Tirumanimuttar sub-basin, carried out monthly on an annual basis for the 75% water year dependable flow, without ground water considerations [refer Table 4.10.12(a)], the sub-basin was found short of water in the months of June to September and January to May, where as the sub-basin is surplus

in its water resources in the months of October, November and December. The maximum deficit of 147.3 MCM (4%) occurred in the sub-basin in the month of March, while the minimum deficit of 37.17 MCM (1.0%) occurred in the sub-basin in the month of January. The maximum surplus of 267.5 MCM (7.3%) occurred in the month of October, while the minimum surplus of 50.49 MCM (1.4%) occurred in the month of December. The annual deficit in the sub-basin is 225.54 MCM (6%).

#### 4.5.1.13 Ponnanai Ar Sub-basin

For the water balance studies carried out monthly on an annual basis for Ponnanai sub-basin for the 75% water year dependable flow, without ground water consideration [refer Table 4.10.13(a)], the sub-basin was found short of water in the months of June to September and January to May, where as the sub-basin is surplus in its water resources in the months of October, November and December. The maximum deficit of 18.84 MCM (1.9%) occurred in the sub-basin in the month of July, while minimum deficit of 1.59 MCM (0.20 %) occurred in the sub-basin in the month of December. The maximum surplus of 43.78 MCM (4.5%) occurred in the month of November, while the minimum surplus of 0.19 MCM (0.02%) occurred in the month of February. The annual deficit in the sub-basin is 13.54 MCM (1.4%).

# 4.5.1.14 Upper Coleroon Sub-basin

In the case of water balance studies of Upper Coleroon sub-basin, carried out monthly on an annual basis for the 75% water year dependable flow, without ground water considerations [refer Table 4.10.14(a)], the sub-basin was found short of water in the months of June to September and February to April, where as the sub-basin is surplus in its water resources in the months of October to January. The maximum

deficit of 69.07 MCM (1.9%) occurred in the sub-basin in the month of July, while the minimum deficit of 2.80 MCM (0.20 %) occurred in the sub-basin in the month of June. The maximum surplus of 132.5 MCM (9.8%) occurred in the month of November, while the minimum surplus of 4.80 MCM (0.40%) occurred in the month of May. The annual surplus in the sub-basin is 86.64 MCM (6%).

## 4.5.1.15 Lower Coleroon Sub-basin

For the water balance studies carried out monthly on an annual basis for Lower Coleroon sub-basin for the 75% water year dependable flow, without ground water consideration [refer Table 4.10.15(a)], it was found that the sub-basin is surplus in its water resources throughout the year. The maximum surplus of 46.01 MCM (0.38%) occurred in the month of September, while the minimum surplus of 2.80 MCM (0.02%) occurred in the month of May. The annual surplus in the sub-basin is 222.2 MCM (2%).

## 4.5.1.16 Cauvery Delta Sub-basin

In the case of water balance studies of Cauvery Delta sub-basin, carried out monthly on an annual basis for the 75% water year dependable flow, without ground water considerations [refer Table 4.10.16(a)], it was found that the sub-basin is surplus in its water resources throughout the year. The maximum surplus of 256.40 MCM (2.6%) occurred in the month of September, while the minimum surplus of 10.45 MCM (0.10%) occurred in the month of May. The annual surplus in the sub-basin is 1203.1 MCM (12%).

4.5.2 The sub-basin wise analysis of the water balance studies for the 75% water year dependable flows, with ground water considerations, for the Cauvery river basin is as follows:

## 4.5.2.1 Upper Cauvery Sub-basin

In the case of water balance studies of Upper Cauvery sub-basin, carried out monthly on an annual basis for the 75% water year dependable flow, with ground water considerations [refer Table 4.10.1(b)], the sub-basin was found short of water in the months of June and September to April, where as the sub-basin is surplus in its water resources in the months of July, August and May. The maximum deficit of 276.1 MCM (6%) occurred in the sub-basin in the month of October, while the minimum deficit of 9.87 MCM (0.20 %) occurred in the sub-basin in the month of November. The maximum surplus of 705.08 MCM (14%) occurred in the month of July, while the minimum surplus of 18.00 MCM (0.40%) occurred in the month of May. The annual surplus in the sub-basin is 304.05 MCM (6%).

#### 4.5.2.2 Kabini Sub-basin

For the water balance studies carried out monthly on an annual basis for Kabini sub-basin for the 75% water year dependable flow, with ground water considerations [refer Table 4.10.2(b)], it was found that in the sub-basin deficits occurred in the months of September and December to March, while the surpluses occurred in the months of June, July, August, October, November, April and May. The maximum deficit of 201.6 MCM (4.1%) occurred in the sub-basin in the month of January, while minimum deficit of 0.47 MCM (0.02 %) occurred in the sub-basin in the month of September. The maximum surplus of 193.24 MCM (3.9%) occurred in the month of August, while the minimum surplus of 0.05 MCM (0.01%) occurred in the month of April. The annual surplus in the sub-basin is 118.62 MCM (2.4%).

#### 4.5.2.3 Shimsha Sub-basin

For the water balance studies carried out monthly on an annual basis for Shimsha sub-basin for the 75% water year dependable flow, with ground water consideration [refer Table 4.10.3(b)], it was found that in the sub-basin deficits occurred in the months of April, while the surpluses occurred in the remaining months throughout the year. The maximum deficit of 1.03 MCM (0.01%) occurred in the sub-basin in the month of April. The maximum surplus of 301.47 MCM (7.8%) occurred in the month of October, while the minimum surplus of 3.94 MCM (0.1%) occurred in the month of March. The annual surplus in the sub-basin is 657.95 MCM (17%).

#### 4.5.2.4 Arkavathi Sub-basin

In the case of water balance studies of Arkavathi sub-basin, carried out monthly on an annual basis for the 75% water year dependable flow, with ground water considerations [refer Table 4.10.4(b)], the sub-basin was found short of water through out the year except the months of September and October. The maximum deficit of 149.2 MCM (7.6%) occurred in the sub-basin in the month of January, while the minimum deficit of 24.58 MCM (1.30 %) occurred in the sub-basin in the month of May. The maximum surplus of 16.73 MCM (0.9%) occurred in the month of October, while the minimum surplus of 5.11 MCM (0.3%) occurred in the month of September. The annual deficit in the sub-basin is 695.7 MCM (35%).

#### 4.5.2.5 Middle Cauvery Sub-basin

For the water balance studies carried out monthly on an annual basis for Middle Cauvery sub-basin for the 75% water year dependable flow, with ground water considerations [refer Table 4.10.5(b)], it was found that in the sub-basin deficits

occurred in the months of May and June, while the surpluses occurred in the months of July to April. The maximum deficit of 1.83 MCM (0.1%) occurred in the sub-basin in the month of May, while minimum deficit of 0.85 MCM (0.003 %) occurred in the sub-basin in the month of June. The maximum surplus of 52.90 MCM (2.4%) occurred in the month of September, while the minimum surplus of 2.54 MCM (0.10%) occurred in the month of April. The annual surplus in the sub-basin is 274 MCM (12%).

#### 4.5.2.6 Suvarnavathi Sub-basin

In the case of water balance studies of Suvarnavathi sub-basin, carried out monthly on an annual basis for the 75% water year dependable flow, with ground water considerations [refer Table 4.10.6(b)], the sub-basin was found short of water in the months of June to August and December to May, where as the sub-basin is surplus in its water resources in the months of September, October and November. The maximum deficit of 6.05 MCM (0.8%) occurred in the sub-basin in the month of January, while the minimum deficit of 0.22 MCM (0.01 %) occurred in the sub-basin in the month of May. The maximum surplus of 7.32 MCM (1.0%) occurred in the month of October, while the minimum surplus of 3.13 MCM (0.40%) occurred in the month of September. The annual deficit in the sub-basin is 17 MCM (2%).

#### 4.5.2.7 Palar Sub-basin

For the water balance studies carried out monthly on an annual basis for Palar sub-basin for the 75% water year dependable flow, with ground water considerations [refer Table 4.10.7(b)], the sub-basin was found short of water in the months of July and November to April, where as the sub-basin is surplus in its water resources in the months of June, August, September, and October. The maximum deficit of 11.86 MCM

(3.3%) occurred in the sub-basin in the month of February, while minimum deficit of 2.88 MCM (0.80%) occurred in the sub-basin in the month of April. The maximum surplus of 10.59 MCM (3.0%) occurred in the month of September, while the minimum surplus of 0.19 MCM (0.10%) occurred in the month of May. The annual deficit in the sub-basin is 22 MCM (6%).

#### 4.5.2.8 Chinnar Sub-basin

In the case of water balance studies of Chinnar sub-basin, carried out monthly on an annual basis for the 75% water year dependable flow, with ground water considerations [refer Table 4.10.8(b)], the sub-basin was found short of water throughout the year. The maximum deficit of 4309.00 MCM (32%) occurred in the sub-basin in the month of October, while the minimum deficit of 150.00 MCM (1.0 %) occurred in the sub-basin in the month of July. The annual deficit in the sub-basin is 12925 MCM (95%).

#### 4.5.2.9 Bhavani Sub-basin

In the case of water balance studies of Bhavani sub-basin, carried out monthly on an annual basis for the 75% water year dependable flow, with ground water considerations [refer Table 4.10.9(b)], the sub-basin was found short of water in the months of June, August, September and January to May, where as the sub-basin is surplus in its water resources in the months of July, October, November and December. The maximum deficit of 137.4 MCM (4.8%) occurred in the sub-basin in the month of March, while the minimum deficit of 7.69 MCM (0.30 %) occurred in the sub-basin in the month of September. The maximum surplus of 99.72 MCM (3.50%) occurred in the month of November, while the minimum surplus of 22.65 MCM (0.8%) occurred in the month of July. The annual deficit in the sub-basin is 237.39 MCM (8%).

#### 4.5.2.10 Novil Sub-basin

For the water balance studies carried out monthly on an annual basis for Noyil sub-basin for the 75% water year dependable flow, with ground water considerations [refer Table 4.10.10(b)], it was found that in the sub-basin deficits occurred in the months of June to September and January to May, while the surpluses occurred in the months of October, November and December. The maximum deficit of 41.33 MCM (3.4%) occurred in the sub-basin in the month of June, while minimum deficit of 9.54 MCM (0.8 %) occurred in the sub-basin in the month of September. The maximum surplus of 106.6 MCM (8.7%) occurred in the month of October, while the minimum surplus of 24.17 MCM (2.0%) occurred in the month of December. The annual deficit in the sub-basin is 31.52 MCM (3%).

#### 4.5.2.11 Amaravathi Sub-başin

For the water balance studies carried out monthly on an annual basis for Amaravathi sub-basin for the 75% water year dependable flow, with ground water consideration [refer Table 4.10.11(b)], the sub-basin was found short of water in the months of June to September and January to May, where as the sub-basin is surplus in its water resources in the months of October, November and December. The maximum deficit of 170.7 MCM (6.2%) occurred in the sub-basin in the month of March, while minimum deficit of 18.6 MCM (0.7 %) occurred in the sub-basin in the month of September. The maximum surplus of 191.4 MCM (7.1%) occurred in the month of November, while the minimum surplus of 126.6 MCM (4.60%) occurred in the month of October. The annual deficit in the sub-basin is 438.6 MCM (16%).

#### 4.5.2.12 Tirumanimuttar Sub-basin

In the case of water balance studies of Tirumanimuttar sub-basin, carried out monthly on an annual basis for the 75% water year dependable flow, with ground water considerations [refer Table 4.10.12(b)], the sub-basin was found short of water in the months of June to September and January to May, where as the sub-basin is surplus in its water resources in the months of October, November and December. The maximum deficit of 79.73 MCM (2.1%) occurred in the sub-basin in the month of March, while the minimum deficit of 26.28 MCM (0.7%) occurred in the sub-basin in the month of January. The maximum surplus of 293.1 MCM (7.7%) occurred in the month of October, while the minimum surplus of 71.65 MCM (1.9%) occurred in the month of December. The annual surplus in the sub-basin is 124.24 MCM (3%).

#### 4.5.2.13 Ponnanai Ar Sub-basin

For the water balance studies carried out monthly on an annual basis for Ponnanai sub-basin for the 75% water year dependable flow, with ground water consideration [refer Table 4.10.13(b)], the sub-basin was found that the sub-basin is surplus in its water resources throughout the year. The sub-basin has been changed from water deficit for some months to water surplus throughout the year. The maximum surplus of 67.79 MCM (6.75%) occurred in the month of November, while the minimum surplus of 0 MCM (0.0%) occurred in the month of April. The annual surplus in the sub-basin is 193.69 MCM (19%).

## 4.5.2.14 Upper Coleroon Sub-basin

In the case of water balance studies of Upper Coleroon sub-basin, carried out monthly on an annual basis for the 75% water year dependable flow, with ground water

considerations [refer Table 4.10.14(b)], the sub-basin was found short of water in the months of July, August, March and April, where as the sub-basin is surplus in its water resources in the months of June, September to February. The maximum deficit of 12.36 MCM (0.9%) occurred in the sub-basin in the month of July, while the minimum deficit of 0.47 MCM (0.01 %) occurred in the sub-basin in the month of August. The maximum surplus of 148.1 MCM (10.8%) occurred in the month of November, while the minimum surplus of 0.59 MCM (0.40%) occurred in the month of June. The annual surplus in the sub-basin is 339.2 MCM (25%).

# 4.5.2.15 Lower Coleroon Sub-basin

For the water balance studies carried out monthly on an annual basis for Lower Coleroon sub-basin for the 75% water year dependable flow, with ground water considerations [refer Table 4.10.15(b)], it was found that the sub-basin is surplus in its water resources throughout the year. The maximum surplus of 74.34 MCM (5.7%) occurred in the month of September, while the minimum surplus of 3.1 MCM (0.02%) occurred in the month of May. The annual surplus in the sub-basin is 342.76 MCM (26%).

# 4.5.2.16 Cauvery Delta Sub-basin

In the case of water balance studies of Cauvery Delta sub-basin, carried out monthly on an annual basis for the 75% water year dependable flow, with ground water considerations [refer Table 4.10.16(b)], it was found that the sub-basin is surplus in its water resources throughout the year. The maximum surplus of 352.2 MCM (3.5%) occurred in the month of September, while the minimum surplus of 11.44 MCM (0.10%) occurred in the month of May. The annual surplus in the sub-basin is 1611 MCM (16%).

# 4.6 ANALYSIS OF WATER BALANCE STUDIES FOR THE 75%, 50%, 90% AND 100% WATER YEAR DEPENDABLE FLOWS

The water balance studies are carried out on the monthly basis, for with and without considerations of ground water for a normal year, i.e., the 75% water year dependable flow.

The water balance studies for two water deficit years and one water surplus year, i.e., 90% and 100%, and 50% water year dependable flows, respectively, are also carried out.

The water balances of each sub-basin were compared with and without consideration of ground water. The sub-basin wise analysis of the water balance studies for the 75%, 50%, 90% and 100% water year dependable flows for the Cauvery river basin is as follows:

# 4.6.1 Upper Cauvery Sub-basin

By comparing monthly water balances in the various water year dependable flows in the Upper Cauvery sub-basin [Refer Table 4.10.1(a) to Table 4.10.1(h)], it is found that the months of July and May are surplus, in the water availability in comparison to the water needs in the sub-basin, with the consideration of ground water availability in all the four water year dependable flows and it is water deficit in the months of September, December and February in all four water year dependable flows. The maximum water surplus of 704 MCM (40%) is in the month of July for a normal year, i.e., the 75% water year dependable flow and the maximum water deficit of 291 MCM is in the month of August for the 100% water year dependable flow with the ground water availability considerations. The sub-basin has become water deficit from water surplus sub-basin in the month of August from 75% water year dependable to

other water year dependable flows.

The amount of annual surplus and annual deficit water has decreased from 3940 MCM and 286 MCM to -262 MCM and -1935 MCM in the sub-basin with the ground water availability for 50%, 75% 90% and 100% water year dependable flows, respectively.

#### 4.6.2 Kabini Sub-basin

In the Kabini sub-basin [Refer Table 4.10.2(a) to Table 4.10.2(h)], it is found that the months of June, October and May are surplus in the water availability in comparison to the water needs in the sub-basin, with the consideration of ground water availability and in months of December, January, February and March are water deficit with the ground water availability considerations in all four water year dependable flows. The maximum water surplus is 446 MCM in the month of May for 100% water year dependable flow and the maximum water deficit is 203 MCM in the month of January for 75% water year dependable flow.

The sub-basin has become water deficit sub-basin from water surplus sub-basin in the month of August from 192 MCM, 219 MCM to -16 MCM and -103 MCM for 75%, 50%, 90% and 100% water year dependable flows, respectively.

The amount of annual surplus and annual deficit water has decreased from 835 MCM and 108 MCM to -487 MCM and -1535 MCM in the sub-basin with the ground water availability for 50%, 75% 90% and 100% water year dependable flows, respectively.

#### 4.6.3 Shimsha Sub-basin

In the Shimsha sub-basin [Refer Table 4.10.3(a) to Table 4.10.3(h)], it is found

that in all the months the water availability is excess than water requirements, very few months are deficit in the water availability in comparison to the water needs in the sub-basin with the consideration of ground water availability. The maximum water surplus of 372 MCM is in the month of October for 50% water year dependable flow and maximum water deficit of 4 MCM is in the month of April for 100% water year dependable flow with the ground water availability considerations.

The amount of annual surplus water has decreased from 783 MCM to 640 MCM, 628 MCM and 341 MCM in the sub-basin with the ground water availability for 50%, 75% 90% and 100% water year dependable flows, respectively.

#### 4.6.4 Arkavathi Sub-basin

In the Arkavathi sub-basin [Refer Table 4.10.4(a) to Table 4.10.4(h)], it is found that in all the months of are deficit in the water availability in comparison to the water needs in the sub-basin, with the consideration of ground water availability. The maximum water deficit of 226 MCM is in the month of September for 90% water year dependable flow.

The amount of annual deficit water is 594 MCM, 713 MCM, 796 MCM and 415 MCM in the sub-basin with the ground water availability for 50%, 75% 90% and 100% water year dependable flows, respectively.

# 4.6.5 Middle Cauvery Sub-basin

In the Middle Cauvery sub-basin [Refer Table 4.10.5(a) to Table 4.10.5(h)], it is found that the months of June and May are deficit in the water availability in comparison to the water needs in the sub-basin, and other months are surplus in the water availability in comparison to the water needs in the sub-basin with the

The maximum water surplus 58 MCM is in the month of September for 50% water year dependable flows.

The amount of annual surplus water is 331 MCM, 269 MCM, 215 MCM and 128 MCM in the sub-basin with the ground water availability for 50%, 75% 90% and 100% water year dependable flows, respectively.

#### 4.6.6 Suvarnavathi Sub-basin

In the Suvarnavathi sub-basin [Refer Table 4.10.6(a) to Table 4.10.6(h)], it is found that the months of September, October and November are surplus for 75% and 50% water year dependable flows and other months are deficit in the water availability in comparison to the water needs in the sub-basin, with the consideration of ground water availability. The maximum water surplus 19 MCM is in the month of October in 50% water year dependable flow and for 90% and 100% water year dependable flows sub-basin is water deficit throughout the year.

The amount of annual surplus and annual deficit water has decreased from 12 MCM to -22 MCM, -50 MCM and -60 MCM in the sub-basin with the ground water availability for 50%, 75% 90% and 100% water year dependable flows, respectively.

# 4.6.7 Palar Sub-basin

In the Palar sub-basin [Refer Table 4.10.7(a) to Table 4.10.7(h)], it is found that the months of November to May are deficit in the water availability in comparison to the water needs in the sub-basin, with the consideration of ground water availability in all the four water year dependable flows. The maximum water surplus 29 MCM is in

the month of September in 50%water year dependable flow and maximum water deficit of 18 MCM is in the month of August in 100%water year dependable flow. In the moth of August the sub-basin becomes water deficit in 90% and 100% water year dependable flow from water surplus in 75% and 50% water year dependable flows.

The amount of annual surplus and annual deficit water has decreased from 44 MCM to -28 MCM, -61 MCM and -115 MCM in the sub-basin with the ground water availability for 50%, 75% 90% and 100% water year dependable flows, respectively.

# 4.6.8 Chinnar Sub-basin

In the Chinnar sub-basin [Refer Table 4.10.8(a) to Table 4.10.8(h)], it is found that all the months are deficit in the water availability in comparison to the water needs in the sub-basin, with the consideration of ground water availability in all four water year dependable flows. The maximum water deficit of 5294 MCM is in the month of October in 50% water year dependable flow.

The amount of annual deficit water is -15787 MCM, -12932 MCM, -13012 MCM and -13155 MCM in the sub-basin with the ground water availability for 50%, 75% 90% and 100% water year dependable flows, respectively.

## 4.6.9 Bhavani Sub-basin

In the Bhavani sub-basin [Refer Table 4.10.9(a) to Table 4.10.9(h)], it is found that the months of October, November and December are surplus and the months of June, August, February, March and April are deficit in the water availability in comparison to the water needs in the sub-basin, with the consideration of ground water availability in all the four water year dependable flows. The maximum water surplus

157 MCM is in the month of October in 50% water year dependable flow and maximum water deficit of 144 MCM is in the month of August in 100% water year dependable flow with the ground water availability considerations.

The amount of annual surplus and annual deficit water has decreased from 239 MCM to -247 MCM, -652 MCM and -947 MCM in the sub-basin with the ground water availability for 50%, 75% 90% and 100% water year dependable flows, respectively.

# 4.6.10 Noyil Sub-basin

In the Noyil sub-basin [Refer Table 4.10.10(a) to Table 4.10.10(h)], it is found that the months of October, November and December are surplus and the months of June, July, August, September, January, February, March, April and May are deficit in the water availability in comparison to the water needs in the sub-basin, with the consideration of ground water availability in all the four water year dependable flows. The maximum water surplus 108 MCM is in the month of October in 50% water year dependable flow and maximum water deficit of 45 MCM is in the month of June in 50% water year dependable flow with the ground water availability considerations.

The amount of annual deficit water is -65 MCM, -40 MCM, -52 MCM and -64 MCM in the sub-basin with the ground water availability for 50%, 75% 90% and 100% water year dependable flows, respectively.

#### 4.6.11 Amaravathi Sub-basin

In the Amaravathi sub-basin [Refer Table 4.10.11(a) to Table 4.10.11(h)], it is found that the months of October and November are surplus and the months of June,

July, August, January, February, March and April are deficit in the water availability in

comparison to the water needs in the sub-basin, with the consideration of ground water availability in all the four water year dependable flows. The maximum water surplus 195 MCM is in the month of November in 50% water year dependable flow and maximum water deficit of 172 MCM is in the month of March in 50% water year dependable flow with the ground water availability considerations. In the month of December the sub-basin becomes water deficit in 90% and 100% water year dependable flows from water surplus in 50% and 75% water year dependable flows.

The amount of annual deficit water is -304 MCM, -454 MCM, -547 MCM and -711 MCM in the sub-basin with the ground water availability for 50%, 75% 90% and 100% water year dependable flows, respectively.

#### 4.6.12 Tirumanimuttar Sub-basin

In the Tirumanimuttar sub-basin [Refer Table 4.10.12(a) to Table 4.10.12(h)], it is found that in the months of October, November and December are surplus in the water availability in comparison to the water needs in the sub-basin, and other months are deficit in the water availability in comparison to the water needs in the sub-basin with the consideration of ground water availability for all the four water year dependable flows. The maximum water surplus 531 MCM is in the month of October for 50% water year dependable flow and in the month of March deficit 82 MCM for 90% water year dependable flow is in the water availability in comparison to the water needs in the sub-basin, with the consideration of ground water availability.

The amount of annual surplus water has decreased from 583 MCM to 219 MCM, 76 MCM and 17 MCM in the sub-basin with the ground water availability for 50%, 75% 90% and 100% water year dependable flows, respectively.

# 4.6.13 Ponnanai Ar Sub-basin

In the Ponnanai Ar sub-basin [Refer Table 4.10.13(a) to Table 4.10.13(h)], it is found that all the months are surplus in the water availability in comparison to the water needs in the sub-basin, with the consideration of ground water availability except the months of April and May in 100% water year dependable flow. The maximum water surplus 85 MCM is in the month of November in 50% water year dependable flow and maximum water deficit of 2 MCM is in the month of April in 100% water year dependable flow.

The amount of annual surplus water has decreased from 244 MCM to 217 MCM, 157 MCM and 61 MCM in the sub-basin with the ground water availability for 50%, 75% 90% and 100% water year dependable flows, respectively.

## 4.6.14 Upper Coleroon Sub-basin

In the Upper Coleroon sub-basin [Refer Table 4.10.14(a) to Table 4.10.14(h)], it is found that the months of October, November and December are surplus and the month of June, is deficit in the water availability in comparison to the water needs in the sub-basin, with the consideration of ground water availability in all the four water year dependable flows. The maximum water surplus 192 MCM is in the month of November in 50% water year dependable flow and maximum water deficit of 37 MCM is in the month of June in 100% water year dependable flow with the ground water availability considerations. In the month of August the sub-basin becomes water deficit in 90% and 100% water year dependable flows from water surplus in 50% and 75% water year dependable flows.

The amount of annual surplus and annual deficit water has decreased from 508 MCM, 358 MCM, 243 MCM to -65 MCM in the sub-basin with the ground water

availability for 50%, 75% 90% and 100% water year dependable flows, respectively.

## 4.6.15 Lower Coleroon Sub-basin

In the Lower Coleroon sub-basin [Refer Table 4.10.15(a) to Table 4.10.15(h)], it is found that in any month no deficit in the water availability in comparison to the water needs in the sub-basin, with the consideration of ground water availability for all four water year dependable flows. The maximum water surplus 102 MCM is in the month of September in 50% water year dependable flow.

The amount of annual surplus water has decreased from 485 MCM to 340 MCM, 285 MCM and 183 MCM in the sub-basin with the ground water availability for 50%, 75% 90% and 100% water year dependable flows, respectively.

# 4.6.16 Cauvery Delta Sub-basin

In the Cauvery Delta sub-basin [Refer Table 4.10.16(a) to Table 4.10.16(h)], it is found that in any month no deficit in the water availability in comparison to the water needs in the sub-basin, with the consideration of ground water availability for all four water year dependable flows except in the month of May in 90% and 100% water year dependable flows. The maximum water surplus 192 MCM is in the month of September in 50% water year dependable flow.

The amount of annual surplus water has decreased from 2121 MCM to 1413 MCM, 952 MCM and 554 MCM in the sub-basin with the ground water availability for 50%, 75% 90% and 100% water year dependable flows, respectively.

## 4.7 WATER BALANCE OF CAUVERY BASIN AS A WHOLE

The detailed water balance studies carried out monthly on annual basis for all the 16 sub-basins in the Cauvery river basin for 75%, 50%, 90%, and 100% water year

dependable flows, with and without considerations of ground water are presented in the Tables 4.10.1(a) to Table 4.10.4(h). The abstracts of the sub-basinwise annual water balance studies for Cauvery basin for 75%, 50%, 90% and 100% water year dependable flows without and with considerations of ground water, are presented in Table 4.11.1 to Table 4.11.4. The abstract of annual water balance for Cauvery basin as a whole for 75%, 50%, 90% and 100% water year dependable flows without and with ground water considerations is presented in table 4.11.5. The sub-basin wise annual water balance for 75%, 50%, 90% and 100% water year dependable flows without and with ground water are presented in Table 4.12.1 to Table 4.12.4. The sub-basinwise monthly deficits/surpluses for 75%, 50%, 90%, and 100% water year dependable flows, with and without considerations of ground water are presented in the Table 4.13.1 to Table 4.13.4. The sub-basinwise monthly deficits or surpluses in descending order with percent of deficit or surplus for 75%, 50%, 90%, and 100% water year dependable flows, with and without considerations of ground water are presented in the Table 4.14.1 to Table 4.14.16. The graphical presentations of the monthly water deficits-surpluses for all the 16 sub-basins in the Cauvery river-basin, without and with ground water considerations are presented in the Figures 4.4.1 to 4.4.16. STATE OF THE

Table 4.10.1(a): Upper Cauvery Sub-basin-Monthly Water Balance for 75% Water Year Dependable Flow, Without Ground Water
