#### LINEAR PROGRAMMING MODEL

#### 5.1 INTRODUCTION

Operation research or system engineering provides methodologies for studying and analyzing various aspects of a complex river basin system, by using mathematical models or computer models. The linear programming and its offshoots are probably the most widely used methods of operation research. It also assists in decision-making process by selecting the best alternative policies subject to all pertinent constraints by simulation and optimization techniques.

A mathematical model is a set of equations that describes and represents the real system. Out of several mathematical programming techniques, linear programming (LP) has been widely used in the optimization of water resources systems for very obvious reasons of large number of variables are involved in a complex water resources problems.

Linear programming is a powerful mathematical technique in decision making to determine the monthly or seasonal releases from canal/reservoir, to allocate irrigated area so that the annual utilization of the available water resources among various uses can be maximized. The task of the linear programming model is to analyze the whole range of development alternatives in a river basin. To perform this task, a linear programming model for multipurpose, multi reservoir and multi-irrigated area proposed to be investigated in this study has to be as realistic as possible.

Some of the assumptions, which have been made for ease of formulation are:

1. The objective function and the constraints are in linear form,

- 2. It is deterministic in nature, i.e., hydrologic inputs are taken as known values and are certain to occur, and
- 3. The model is to be run for one representative year only at a time.

Major design variables/parameters considered are:

- 1. Capacity of the reservoir,
- The area sown for each crop,
- The annual amount of upstream water for irrigation and water supply (municipal and industrial uses),
- 4. The annual amount of downstream water for irrigation and water supply (municipal and industrial uses), and
- 5. Capacity of the associated canal system.

A LP model is formulated below:

#### 5.2 OBJECTIVE FUNCTION

A sample site is shown in Figure 5.1. The variables/ parameters of a reservoir are shown in Figure 5.2.

For linear programming model the following 4 single objective functions are considered individually:

- 1. To maximize the total annual diversions for irrigation and water supply (annual water utilization) from reservoirs (major projects) and remaining areas in each sub-basin not covered by reservoirs.
- 2. To maximize the area to be irrigated at each reservoir,
- 3. To maximize the agricultural food production at each reservoir, and
- 4. To maximize the total annual net benefits from crops at each reservoir.

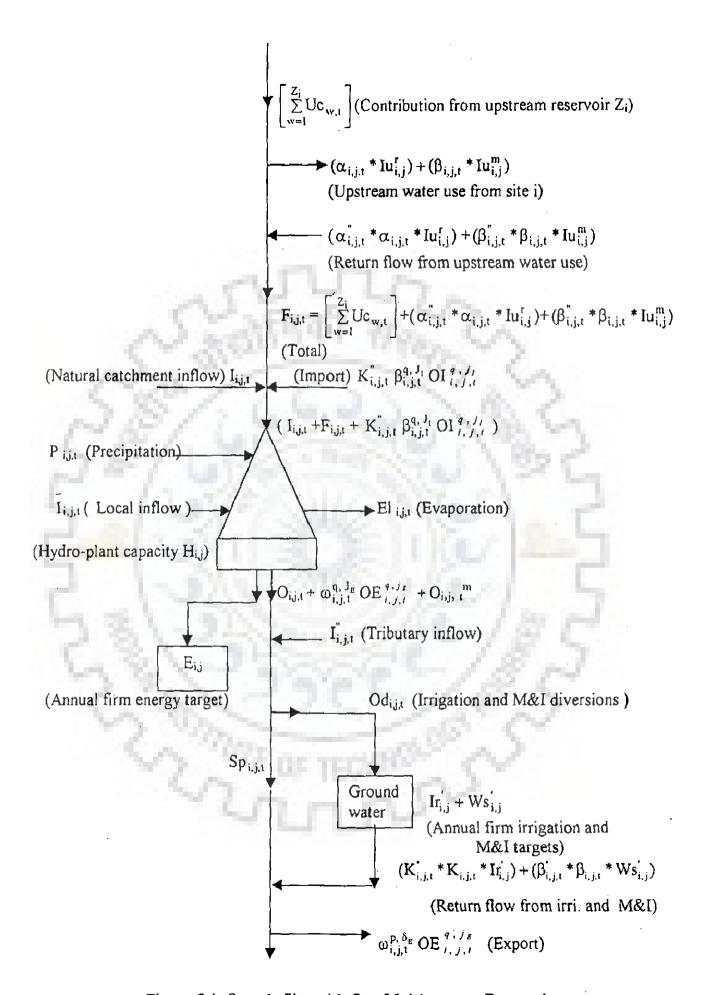

Figure 5.1: Sample Site with One Multipurpose Reservoir.

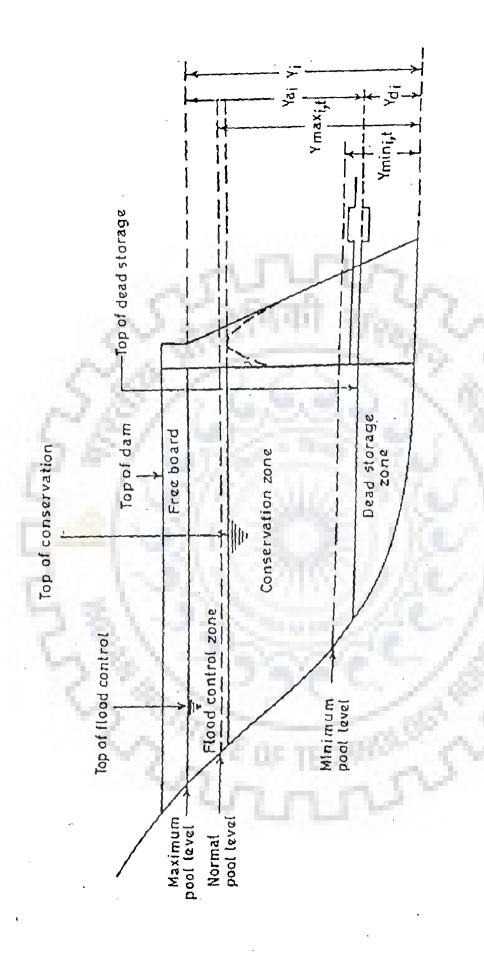

Figure 5.2: Various Reservoir Storage and Variables Related to a Reservoir Site

These objective functions are mathematically written as follows:

(1) To maximize the total annual diversions for irrigation and water supply/ or irrigation (annual water utilization) from reservoirs (major projects) and remaining areas in each sub-basin not covered by reservoirs, i.e.,

1(a)- For lumped irrigation and water supply for entire system:

Max 
$$Z = \sum_{j=1}^{NB} \sum_{i=1}^{N_j} (Ir_{i,j} + Ws_{i,j})$$
 (For lumped irrigation model) (5.2.1-I)

where

| i                 | Reservoir i                                                                                             |
|-------------------|---------------------------------------------------------------------------------------------------------|
| j                 | Sub-basin j                                                                                             |
| Nj                | Number of sites, in sub-basin j                                                                         |
| NB                | Number of sub-basins                                                                                    |
| Ir,               | Total annual reservoir diversions (annual water utilization) for irrigation from site i, in sub-basin j |
| Ws <sub>i,j</sub> | Annual water supply diversion from sites i, sub-basin j                                                 |

1(b)-For each reservoir (major project):

Max 
$$Z = \sum_{i=1}^{12} \sum_{k=1}^{NCI} W_{i,j,i}^{k} * A_{i,j}^{k}$$
 For all i and j (For crop consideration model)

(5.2.1-II)

| W <sup>k</sup><br>i. j. t | Total water diversion requirements in depth for crop k, at site i, in sub-basin j, in time t |
|---------------------------|----------------------------------------------------------------------------------------------|
| i                         | Reservoir i                                                                                  |
| j                         | Sub-basin j                                                                                  |
| k                         | Crop k                                                                                       |
| t ·                       | Time t                                                                                       |
| N <sub>j</sub>            | Number of sites, in sub-basin j                                                              |
| NCI <sup>i. j</sup>       | Total number of irrigated crops at site i, in sub-basin j                                    |
| $A_{i,j}^k$               | Irrigated-cropped area of crop k, at site i, in sub-basin j                                  |

(2) To maximize the area to be irrigated at each reservoir, i. e.,

$$\operatorname{Max} Z = \sum_{k=1}^{\operatorname{NCI}^{k,j}} A_{i,j}^{k}$$
 For all i and j (5.2.2)

where

| i                   | Reservoir i                                                 |
|---------------------|-------------------------------------------------------------|
| j                   | Sub-basin j                                                 |
| k                   | Crop k                                                      |
| NCI <sup>i, j</sup> | Total number of irrigated crops at site i, in sub-basin j   |
| $A_{i,j}^k$         | Irrigated-cropped area of crop k, at site i, in sub-basin j |

(3) To maximize the agricultural food production at each reservoir, i.e.,

Max 
$$Z = \sum_{k=1}^{NCI^{i,j}} A_{i,j}^{k} * y_{i,j}^{k}$$
 For all i and j (5.2.3)

where

| i                   | Reservoir i                                                 |
|---------------------|-------------------------------------------------------------|
| ј                   | Sub-basin j                                                 |
| k                   | Crop k                                                      |
| NCI <sup>i, j</sup> | Total number of irrigated crops at site i, in sub-basin j   |
| $y_{i,j}^k$         | Yield per unit area of crop k, at site i, in sub-basin j    |
| $A_{i,j}^k$         | Irrigated-cropped area of crop k, at site i, in sub-basin j |

4. To maximize the total annual net benefits from crops at each reservoir, i.e.,

Max 
$$Z = \sum_{k=1}^{NCI} A_{i,j}^{k} * y_{i,j}^{k} * b_{i,j}^{k}$$
 For all i and j (5.2.4)

| i | Reservoir i |
|---|-------------|
| j | Sub-basin j |
| k | Crop k      |

| NCI <sup>i, j</sup> | Total number of irrigated crops at site i, in sub-basin j   |
|---------------------|-------------------------------------------------------------|
| $y_{i,j}^k$         | Yield per unit area of crop k, at site i, in sub-basin j    |
| $A_{i,j}^k$         | Irrigated-cropped area of crop k, at site i, in sub-basin j |
| b <sup>k</sup> , j  | Net benefits from crop k, at site i, in sub-basin j         |

#### 5.3 THE CONSTRAINTS

The maximization of the objective function is to be achieved subject to the following constraints:

#### 5.3.1 Reservoir Continuity Equation Constraints

Continuity constraints are those constraints that are included in the model to ensure conservation of mass in a given time. In terms of a river system this means that the water that enters a point on the stream must leave that point on the stream, if it has not been stored in a reservoir or diverted out of the stream for a water use. The basic continuity principle applies throughout the entire reach of the stream for all the times. However, it is necessary to write continuity constraints only at site where water is stored diverted or imported. The continuity relationship for a multi reservoir system at a reservoir site can be written as follows:

$$\begin{split} &K_{i,j,t}^{'}*S_{i,j,t-1}=S_{i,j,t-1}+I_{i,j,t}+F_{i,j,t}+\sum(\psi_{i,j,t}^{q,j_{t}}*TI_{i,j}^{q,j_{t}})\\ &-\sum(\omega_{i,j,t-1}^{q,j_{t}}*TE_{i,j}^{-q,j_{t}})+\sum_{p}\sum_{j_{E}}K_{p,j,t}^{''}(\psi_{i,j,t}^{q,j_{t}}*OI_{i,j,p}^{q,j_{t}})\\ &-\sum_{j_{t}}\sum_{p}(\omega_{i,j,t}^{p,j_{t}}*OE_{i,j}^{-q,j_{t}})+P_{i,j,t}+I_{i,i_{t}}-O_{i,j,t}^{m}-O_{i,j,t}-O_{i,j,t}^{sa}-O_{i,j,t}^{sa}\\ &-(\alpha_{i,j,t}^{q,j_{t}}*Iu_{i,j}^{r,s}+\beta_{i,j,t}^{q,j_{t}}*Iu_{i,j}^{m,h,s})+(\alpha_{i,j,t}^{''}*\alpha_{i,j,t}^{q,j_{t}}*Iu_{i,j}^{r})+(\beta_{i,j,t}^{''}*\beta_{i,j,t}^{q,i_{t}}Iu_{i,j}^{m}) \end{split}$$

For all i, j and t

(5.3.1.1)

$$\begin{split} K_{i,j,t}^{'}*S_{i,j,t} - S_{i,j,t-1} + O_{i,j,t} - F_{i,j,t} - P_{i,j,t} - I_{i,j,t}^{'} - \sum_{i,j,t} (\psi_{i,j,t}^{q,j_{i}} *TI_{i,j}^{q,j_{i}}) + O_{i,j,t}^{se} \\ + \sum_{i} (\omega_{i,j,t}^{q,j_{i}} *TE_{i,j}^{q,j_{i}}) - \sum_{p} \sum_{j_{p}} K_{p,j,t}^{''} (\psi_{i,j,t}^{q,j_{i}} *OI_{i,j,t}^{q,j_{i}}) + \sum_{j_{i}} \sum_{p} (\omega_{i,j,t}^{p,j_{i}} *OE_{i,j}^{q,j_{i}}) \\ + (\alpha_{i,j,t} *Iu_{i,j}^{r,s} + \beta_{i,j,t} *Iu_{i,j}^{m,h,s}) - (\alpha_{i,j,t}^{''} *\alpha_{i,j,t} *Iu_{i,j}^{r}) - (\beta_{i,j,t}^{''} *\beta_{i,j,t} *Iu_{i,j}^{m}) \\ - I_{i,j,t} + O_{i,j,t}^{m} = 0 \end{split}$$
For all i, j and t (Rearranged equation)

The physical meaning of each term in the above equation is defined as below.

| S i, j, 1                | Final storage in the reservoir i, in sub-basin j, in time t                                                             |
|--------------------------|-------------------------------------------------------------------------------------------------------------------------|
| S i, j, t-1              | Initial storage in the reservoir i, in sub-basin j, in time t                                                           |
| K i,j,t                  | Reservoir evaporation coefficient for site i, in sub-basin j, in time t                                                 |
| $I_{i,j,1}$              | Natural catchment inflow to reservoir/site i, in sub-basin j, in time t                                                 |
| F <sub>i, j, t</sub>     | Contribution from upstream reservoirs/sites to the reservoir/site I, in sub-basin j, in time t                          |
| $\Psi_{i,j,k}^{q,j}$     | Percentage of import to reservoir/site i, in sub-basin j, in time t, from site q, of exporting sub-basin j <sub>I</sub> |
| Tl <sub>i.j.t</sub>      | Import to reservoir/site i, in sub-basin j, in time t, from site q, of exporting sub-basin $j_I$                        |
| $\omega_{i,j,1}^{q,j_g}$ | Percentage of export from site/reservoir i, in sub-basin j, in time t, to site q, of importing sub-basin j <sub>E</sub> |
| $TE_{i,j,i}^{q,J_E}$     | Export from site/reservoir i, in sub-basin j, in time t, to site q, of importing sub-basin $j_E$                        |
| $P_{i,j,i}$              | Precipitation directly upon the reservoir i, in sub-basin j, in time t                                                  |
| Ī <sub>i, j, 1</sub>     | Local inflow to the reservoir/site i, from the surrounding area in sub-basin j, in time t                               |
| O <sub>i, j, t</sub>     | Mandatory releases to downstream natural channel from site i, in sub-basin j, in time t                                 |
| $Q_{i,j,t}$              | Release from reservoir/site i, in sub-basin j, in time t                                                                |
| Iu <sub>i, j</sub>       | Total annual upstream irrigation water use targets from surface water of reservoir/site i, in sub-basin j               |
| Ose                      | = Spennae lassee from reservoiriste ; in The tocini in time +                                                           |

Ose = Seepage losses from reservoir/site i, in sub-basinj, in time t

| Iu <sub>i,j</sub> <sup>m,s</sup> | Total annual upstream domestic and industrial water use target from surface water of site i, in sub-basin j |
|----------------------------------|-------------------------------------------------------------------------------------------------------------|
| $K_{i,j,t}$                      | % annual irrigation from site i, in sub-basin j, in time t                                                  |
| K ", j, t                        | Percent of return flow to river from irrigation from site i, in sub-basin j, in time t                      |
| Iu ',                            | Total annual upstream irrigation water use targets of reservoir/site i, in sub-basin j                      |
| Iu m                             | Total annual upstream domestic and industrial water use target of site i, in sub-basin j                    |

(a) The mandatory release should be equal to the percent of the inflow.

$$O_{i,j,t}^{m} - 0.01 * I_{i,j,t} = 0$$
 For all i, j and t (5.3.1.2)

(b) The total annual upstream M&I water use target should equal the sum of total annual upstream M&I water use target from surface water and total annual upstream M&I water use for rural human population and live stock population.

$$Iu \frac{mh}{i, j} + Iu \frac{mt}{i, j} - Iu \frac{m}{i, j} = 0$$
 For all i and j (5.3.1.3)

where

| Iu <sub>i, j</sub> | Total annual upstream domestic water use for rural human population of site i, in sub-basin j |
|--------------------|-----------------------------------------------------------------------------------------------|
| Iu <sub>i,j</sub>  | Total annual upstream domestic water use for livestock population of site i, in sub-basin j   |

(c) The total annual upstream irrigation water use target should equal the sum of annual upstream irrigation water use target from surface water and ground water.

$$Iu_{i,j}^{rg} + Iu_{i,j}^{rs} - Iu_{i,j}^{r} = 0$$
 For all i and j (5.3.1.4)

| Iu <sub>i, j</sub> | Total annual upstream irrigation water use targets from surface water of reservoir/site i, in sub-basin j |
|--------------------|-----------------------------------------------------------------------------------------------------------|
| Iu r               | Total annual upstream irrigation water use targets of reservoir/site i, in sub-basin j                    |

(d) From the annual upstream ground water available the sum of annual upstream water requirement for rural human population from ground water and annual upstream water requirement for live stock population from ground water has been subtracted. The annual upstream irrigation use by ground water should not exceed this quantity.

where

| Og us                                | Annual upstream ground water available for site i, in sub-basin j                                         |
|--------------------------------------|-----------------------------------------------------------------------------------------------------------|
| Iu <sub>i, j</sub> <sup>m, h,g</sup> | Total annual upstream rural human population water use target from ground water of site i, in sub-basin j |

(e) The annual upstream water requirement from ground water for rural population should be 50 percent of the annual upstream M&I water use from ground water.

$$Iu_{i,j}^{mhg} - 0.5Iu_{i,j}^{mh} = 0$$
 For all i and j (5.3.1.6)

where

| Iu <sub>i, j</sub> <sup>m, h,g</sup>                             | Total annual upstream rural human population water use target from ground water of site i, in sub-basin j |
|------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------|
| $\begin{bmatrix} \mathrm{Iu}_{i,j}^{\mathrm{m,h}} \end{bmatrix}$ | Total annual upstream domestic water use for rural human population of site i, in sub-basin j             |

(f) The annual upstream water use for rural population from surface water should be 50 percent of the annual upstream domestic water use for rural human population.

| Iu <sup>m,h,s</sup>                | Total annual upstream domestic water use for rural human population from surface water of site i, in sub-basin j |
|------------------------------------|------------------------------------------------------------------------------------------------------------------|
| Iu <sub>i, j</sub> <sup>m, h</sup> | Total annual upstream domestic water use for rural human population of site i, in sub-basin j                    |

(g) The value of the total inflow to a reservoir/site is the sum of all the downstream contributions made from the upstream reservoirs linked to the reservoir under consideration which includes spills, the return flows from all the irrigation areas and M&I water supply upstream of the reservoir under consideration.

$$F_{i,j,t} = \sum_{w=1}^{Z_{i,j}} \left[ Sp_{w,j,t} + (K_{w,j,t}^{"} * K_{w,j,t} * Ir_{w,j}^{"}) + (\beta_{w,j,t}^{"} * \beta_{w,j,t} * Ws_{w,j}^{"}) + \delta_{w,j,t}^{"} * O_{w,j,t}^{m} \right]$$

$$+ (\alpha_{i,j,t}^{"} * \alpha_{i,j,t} * Iu_{i,j}^{r}) + (\beta_{i,j,t}^{"} * \beta_{i,j,t} * Iu_{i,j}^{m})$$
For all i, j and t
$$[5.3.1.8]$$

| F <sub>i, j, t</sub>   | Contribution from upstream reservoirs/sites to the reservoir/site I, in sub-basin j, in time t |
|------------------------|------------------------------------------------------------------------------------------------|
| w                      | Reservoir / site contributing to the flow of ith downstream reservoir / site                   |
| Z i, j                 | Number of upstream reservoirs contributing to the flow of downstream site i, in sub basin j    |
| Sp w.j.t               | Secondary water release (spill) from site w, in time t                                         |
| K ", '                 | Percent of return flow to river from irrigation from site i, in sub-basin j,                   |
|                        | in time t                                                                                      |
| $K_{w,j,t}$            | Reservoir evaporation from site w, in sub-basin j, in time t                                   |
| lr <sub>w.j</sub>      | Total annual irrigation target from site w, in sub-basin j                                     |
| β " <sub>w, j, t</sub> | Percent of return flow to river from water supply from site i, in sub-basin j, in time t       |

| $\beta_{w,j,t}$        | Percent of annual water supply (Ws' <sub>w,j</sub> ) from site i, in sub-basin j, in time t                   |
|------------------------|---------------------------------------------------------------------------------------------------------------|
| Ws w,j                 | Total annual water supply target from site w, in sub-basin j                                                  |
| δ", , , t              | Percent of downstream mandatory release returning to river from site w, in time t                             |
| O <sub>i. j. t</sub>   | Mandatory releases to downstream natural channel from site i, in sub-basin j, in time t                       |
| $\alpha_{i,j,\dagger}$ | Percent of return flow to river from upstream water use for irrigation of site i, in sub-basin j, in time t   |
| α <sub>i, j, t</sub>   | Percent of annual upstream irrigation water use of site i, in sub-basin j, in time t                          |
| β <sub>i, j, t</sub>   | Percent of return flow to river from upstream water use for domestic use of site i, in sub-basin j, in time t |
| $\beta_{i,j,t}$        | Percent of annual upstream domestic and industrial water use of site i, in sub-basin j, in time t             |
| Iu m                   | Total annual upstream domestic and industrial water use target of site i, in sub-basin j                      |

$$F_{i,j,t} - \sum_{v=1}^{Z_i} \left[ Sp_{v,j,t} + (K_{w,j,t}^{"} * K_{w,j,t} * Ir_{v,j}^{"}) + (\beta_{w,j,t}^{"} * \beta_{w,j,t} * W_{S_{w,j}}) + \delta_{w,j,t}^{"} * O_{w,j,t}^{m} \right]$$

$$- (\alpha_{i,j,t}^{"} * \alpha_{i,j,t} * Iu_{i,j}^{t}) + (\beta_{i,j,t}^{"} * \beta_{i,j,t} * Iu_{i,j}^{m}) = 0$$
For all i, j and t (Rearranged equation)
$$[5:3.1.8]$$

In the model, the storage at the end of the time period t, plus natural catchment inflow, Plus all other possible inflows (sum of all the down stream contributions made from the upstream reservoirs linked to the reservoir under consideration which include spills, the return flows from all the irrigated areas and the municipal and industrial uses upstream of the reservoir under consideration), minus all downstream releases made from the reservoir under consideration. This is some times called a continuous model.

#### 5.3.2 Storage Limits

The contents of the reservoir at any period cannot exceed the capacity of the reservoir, but should be greater than the dead storage of the reservoir, i.e.

$$Yd_{i,j} \le Ymin_{i,j,t} \le S_{i,j,t-1} \le Ymax_{i,j,t} \le Y_{i,j}$$
 For all i, j and t (5.3.2)

| $Yd_{i,j}$            | Dead storage capacity of reservoir/site i, in sub-basin j                                  |
|-----------------------|--------------------------------------------------------------------------------------------|
| Ymin i,j,t            | Gross capacity up to the minimum pool level of reservoir/site i, in sub-basin j, in time t |
| S i, j, t-1           | Initial storage in the reservoir i, in sub-basin j, in time t                              |
| Ymax <sub>i,j,t</sub> | Gross capacity up to the normal pool level of reservoir/site i, in sub-basin j, in time t  |
| $Y_{i,j}$             | Gross storage capacity of reservoir/site i, in sub-basin j                                 |

#### 5.3.3 Reservoir Release Constraints

(a) The volume of the water released from the reservoir must be sufficient to meet the irrigation, domestic and industrial demand during that period by using surface and ground water potential, i.e., where,

$$O_{i,j,t} + I_{i,j,t}^{"} = Od_{i,j,t} + Sp_{i,j,t}$$
 For all i, j and t (5.3.3.1)

where

| O <sub>1, j, l</sub>  | Total release from site i, in sub-basin j, in time t                                                  |
|-----------------------|-------------------------------------------------------------------------------------------------------|
| Ir,                   | Water that joins the main stream just above the irrigation diversion canal-<br>site i, in sub-basin j |
| $Od_{i,j,i}$          | Total release at site i, in sub-basin j, in time t for irrigation and water supply                    |
| Sp <sub>i, j, t</sub> | Secondary water release (spill) from site i, in sub-basin j, in time t                                |

(b) The total release from reservoir in any period for irrigation and M&I water use is equal to release for irrigation and M&I water use.

Od 
$$_{i,j,t} = Od _{i,j,t}^{r} + Od _{i,j,t}^{m}$$
 For all i, j and t (5.3.3.2)

| $Od_{i,j,t}$ | Total release at site i, in sub-basin j, in time t for irrigation and water supply |
|--------------|------------------------------------------------------------------------------------|
| Od [, j, t   | Release at site i, in sub-basin j, in time t, for irrigation                       |
| Od m         | Release at site i, in sub-basin j, in time t, for water supply                     |

(c) Ground water required for irrigation in any period is a fraction of total annual ground water irrigation target.

$$Og'_{i,j,t} = K_{i,j,t} * Ir_{i,j}^{g}$$
 For all i, j and t (5.3.3.3)

where

| Og <sub>i,j,1</sub> | Ground water available for irrigation, from site i, in sub-basin j, in time t |
|---------------------|-------------------------------------------------------------------------------|
| K ,,,,              | % annual irrigation from site i, in sub-basin j, in time t                    |
| $Ir_{i,j}^g$        | Total annual ground water irrigation target from site i, in sub-basin j       |

(d) The release for irrigation use from surface water should be a fraction of the total annual surface water irrigation target.

$$Od_{i, j, t}^{T} = K_{i, j, t}^{*} Ir_{i, j}^{S}$$
 For all i, j and t (5.3.3.4)

where

| $Od_{i,j,t}^r$       | Release at site i, in sub-basin j, in time t, for irrigation             |
|----------------------|--------------------------------------------------------------------------|
| $\mathbf{K}_{i,j,i}$ | % annual irrigation from site i, in sub-basin j, in time t               |
| Ir, s                | Total annual surface water irrigation target from site i, in sub-basin j |

(e) Ground water required for M&I water use in any period should be equal to the sum of the M&I water supply target for urban and industrial water use from ground water.

$$Og_{i,j,t}^{m} = \xi_{i,j,t} (\phi_{i,j}^{U^{g}} W s_{i,j}^{U} + \phi_{i,j}^{I^{g}} W s_{i,j}^{I}) \qquad \text{For all } i, j \text{ and } t$$
 (5.3.3.5)

| Og <sup>m</sup>    | Ground water available for municipal and industrial from site i, in sub-basin j, in time t |
|--------------------|--------------------------------------------------------------------------------------------|
| ξ <sub>i,j,1</sub> | % of annual water use for industrial and urban from site i, in sub-basin j, in time t      |
| $\phi_{i,j}^{U^g}$ | % of annual ground water for urban domestic water requirement from site i, in sub-basin j  |
| Ws U,j             | Annual water requirement for urban domestic use from sites i, in sub-basin j               |
| ф і, ј             | % of annual ground water for industrial requirement from sites i, in sub-basin j           |
| Ws i, j            | Annual water requirement for industrial use from sites i, in sub-basin j                   |

(f) The release for M&I water use in any period should be equal to the sum of the M&I water supply target for urban and industrial water use from surface water.

$$Od_{i,j,t}^{m} = \xi_{i,j,t} (\varphi_{i,j}^{U^{s}} Ws_{i,j}^{U} + \varphi_{i,j}^{I^{s}} Ws_{i,j}^{I}) \qquad \text{For all } i, j \text{ and } t$$
 (5.3.3.6)

where

| Od m i,j,t                     | Release at site i, in sub-basin j, in time t, for water supply                             |
|--------------------------------|--------------------------------------------------------------------------------------------|
| ξ <sub>i,j,1</sub>             | % of annual water use for industrial and urban from site i, in sub-basin j, in time t      |
| $\phi_{i,j}^{U^s}$             | % of annual surface water for urban domestic water requirement from site i, in sub-basin j |
| Ws <sup>U</sup> <sub>i,j</sub> | Annual water requirement for urban domestic use from sites i, in sub-basin j               |
| φ 1 <sup>s</sup>               | % of annual surface water for industrial requirement from sites i, in sub-basin j          |
| Ws !                           | Annual water requirement for industrial use from sites i, in sub-basin j                   |

(g) The annual irrigation target should equal the sum of annual irrigation targets from the surface and ground waters.

$$Ir_{i,j}^{'} = Ir_{i,j}^{s} + Ir_{i,j}^{g}$$
 For all i and j (5.3.3.7)

| Ir ,         | Total annual irrigation target from site i, in sub-basin j               |
|--------------|--------------------------------------------------------------------------|
| $Ir_{i,j}^s$ | Total annual surface water irrigation target from site i, in sub-basin j |
| Ir, g        | Total annual ground water irrigation target from site i, in sub-basin j  |

(h) The annual M&I water use target should equal the sum of annual M&I water use targets from surface and ground water.

$$Ws'_{i,j} = Ws^{U}_{i,j} + Ws^{I}_{i,j}$$
 For all i and j (5.3.3.8)

where

| Ws <sub>i,j</sub>              | Annual water supply diversion from sites i, sub-basin j                              |
|--------------------------------|--------------------------------------------------------------------------------------|
| Ws <sup>U</sup> <sub>i,j</sub> | Annual surface water requirement for urban domestic use from sites i, in sub-basin j |
| Ws <sup>1</sup> <sub>i,j</sub> | Annual surface water requirement for industrial use from sites i,in sub-basin j      |

# 5.3.4 Ground Water Availability Constraints

(a) The total annual downstream water use for irrigation and water supply from ground water should be equal to the annual ground water available in the downstream.

$$\sum_{t} Og_{i,j,t}^{m} + \sum_{t} Og_{i,j,t}^{r} = Og_{i,j}^{ds} \qquad \text{For all i and j} \qquad (5.3.4.1)$$

| Og m           | Ground water available for municipal and industrial from site i, in sub-basin j, in time t |
|----------------|--------------------------------------------------------------------------------------------|
| $Og_{i,j,1}^r$ | Ground water available for irrigation, from site i, in sub-basin j, in time t              |
| Ogi, j         | Annual d/s ground water available for site i, in sub-basin j.                              |

(b) The total annual upstream use for irrigation and water supply from ground water should be equal to the annual ground water available in upstream.

$$Iu_{i,j}^{m,g} + Iu_{i,j}^{r,g} = Og_{i,j}^{us}$$
 For all i and j (5.3.4.2)

where

| Iu <sup>m, g</sup>                 | Total annual upstream M & I water use target from surface water of site i, in sub-basin j      |
|------------------------------------|------------------------------------------------------------------------------------------------|
| lu <sub>i, j</sub> <sup>r, g</sup> | Total annual upstream irrigation water use targets from ground water of site i, in sub-basin j |
| Ogi s                              | Annual upstream ground water available for site i, in sub-basin j.                             |

(c) The annual ground water available at the upstream and downstream of a site should equal to total annual ground water available at the site.

$$Og_{i,j}^{us} + Og_{i,j}^{ds} = Og_{i,j}$$
 For all i and j (5.3.4.3)

where

| Ogi. s             | Annual upstream ground water available for site i, in sub-basin j. |
|--------------------|--------------------------------------------------------------------|
| Ogd s              | Annual d/s ground water available for site i, in sub-basin j.      |
| Og <sub>i, j</sub> | Annual ground water available for site i, in sub-basin j           |

## 5.3.5 Sub-Basin Wise Annual Irrigation Constraints

Annual irrigation diversion from site i, in sub-basin j should not exceed total annual release for irrigation at site i in sub-basin j, i.e.,

$$OC_{i,j}^{r} = \sum_{t=1}^{12} Od_{i,j,t}^{r}$$
 For all i and j (5.3.5)

| $OC_{i,j}^{r}$ | Annual irrigation diversion from site i in sub-basin j. |
|----------------|---------------------------------------------------------|
|                | l f                                                     |

# 5.3. 6 Sub-Basin Wise Annual Water Supply Constraints

Annual water supply diversion from site i, in sub-basin j, should not exceed total annual release for water supply at site i in sub-basin j.

$$OC_{i,j}^{m} = \sum_{t=1}^{12} Od_{i,j,t}^{m}$$
 For all i and j (5.3.6)

where

| OC <sub>i,j</sub> | Annual water supply diversion from site i, in sub-basin j.     |
|-------------------|----------------------------------------------------------------|
| Od in i.j.t       | Release at site i, in sub-basin j, in time t, for water supply |

#### 5.3.7 Total Annual Canal Capacity Constraints

Total annual diversion for irrigation and water supply both at site i in sub-basin j should not exceed the canal capacity. i.e.,

$$(OC_{i,j}^r + OC_{i,j}^m) - CC_{i,j} \le 0$$
 For all i and j (5.3.7) where

| OC T                           | Annual irrigation diversion from site i, in sub-basin j    |
|--------------------------------|------------------------------------------------------------|
| OC <sup>m</sup> <sub>i,j</sub> | Annual water supply diversion from sites i, in sub-basin j |
| CC <sub>i,j</sub>              | Annual capacity of canal at site i, in sub-basin j         |

#### 5.3.8 Land Use Constraints

The total area under crops at any time t should be less than or equal to total available area. i.e.,

$$\sum_{k=1}^{NCI^{i,j}} \lambda_{i,j,t}^{k} * A_{i,j}^{k} \le TA_{i,j}$$
 For all i and j (5.3.8)

| $\lambda_{i,j,t}^{k}$ | Land use coefficient for crop k, for site i in, sub-basin j, in time t |
|-----------------------|------------------------------------------------------------------------|
| $A_{i,j}^k$           | Irrigation area of crop k, for site i, in sub-basin j                  |
| TA <sub>i,j</sub>     | Total culturable command area (CCA) of site i, in sub-basin j          |

#### 5.3.9 Crop Water Requirement Constraints

The water requirements of various crops are made in each month and cannot exceed the monthly availability of surface water and ground water, i.e.,

$$\sum_{k=1}^{NCt^{i,j}} W_{i,j,t}^{k} * A_{i,j}^{k} \le Od_{i,j,t}^{r} + Og_{i,j,t}^{r} \qquad \text{For all } i, j \text{ and } t$$
 (5.3.9)

where

| $W_{i,j,t}^k$                  | Water requirement for crop k, at site i, in sub-basin j, in time t            |
|--------------------------------|-------------------------------------------------------------------------------|
| A <sup>k</sup> <sub>i, j</sub> | Irrigation area of crop k, for site i, in sub-basin j                         |
| Od i, j, t                     | Release at site i, in sub-basin j, in time t, for irrigation                  |
| Og <sub>i,j,t</sub>            | Ground water available for irrigation, from site i, in sub-basin j, in time t |

## 5.3.10 Food Self-Sufficiency Constraints

The food production at each reservoir in the sub-basin/basin should be sufficient enough to meet requirements of the people living in the sub-basin/basin, taking their habits, i.e.,

#### (i) For cereal crops constraints

$$\sum_{k=1}^{NCT} A_{i,j}^{k} * y_{i,j}^{k} \ge FC_{i,j}$$
 For all i and j (5.3.10.1)

| $A_{i,j}^k$       | Irrigation area of crop k, for site i, in sub-basin j                                   |
|-------------------|-----------------------------------------------------------------------------------------|
| y k i,j           | Yield per quintal per hector area of crop k, from site i, in sub-basin j                |
| FC <sub>i,j</sub> | Cereal food requirements of the people living in the area of site i, in sub-<br>basin j |

#### (ii) For pulses crops constraints

$$\sum_{k=1}^{NCI_{i,j}^{P}} A_{i,j}^{k} * y_{i,j}^{k} \ge FP_{i,j}$$
 For all i and j (5.3.10.2)

#### where

| $A_{i,j}^k$ | Irrigation area of crop k, for site i, in sub-basin j                                   |
|-------------|-----------------------------------------------------------------------------------------|
| y k         | Yield per quintal per hector area of crop k, from site i, in sub-basin j                |
| $FP_{i,j}$  | Pulses food requirements of the people living in the area of site i, in sub-<br>basin j |

# (iii) For oilseed crops constraints

$$\sum_{k=1}^{NCI_{i,j}^{O}} A_{i,j}^{k} * y_{i,j}^{k} \ge FO_{i,j}$$
 For all i and j (5.3.10.3)

#### where

| A <sub>i, j</sub> | Irrigation area of crop k, for site i, in sub-basin j                                 |
|-------------------|---------------------------------------------------------------------------------------|
| $y_{i,j}^k$       | Yield per quintal per hector area of crop k, from site i, in sub-basin j              |
| FO <sub>i,j</sub> | Oilseed crops requirements of the people living in the area of site i, in sub-basin j |

# (iv) Upper and lower crop areas constraint

$$LL_{i, j}^{k} \le A_{i, j}^{k} \le UL_{i, j}^{k}$$
 For all i, j and k (5.3.10.4)

| $LL_{i,j}^{k}$ | Lower limit of crop area at site i, in sub basin j    |
|----------------|-------------------------------------------------------|
| A <sup>k</sup> | Irrigation area of crop k, for site i, in sub-basin j |
| $UL_{i,j}^k$   | Upper limit of crop area at site i, in sub basin j    |

#### 5.3.11 Hydroelectric Energy Constraints

The production of hydroelectric energy is a relatively well defined technical process.

There are only three decision variables which affect-

- (i) The flow through the turbine of the power plant,
- (ii) The head associated with flow, and
- (iii) The capacity of power plant.

The relationships of these variables to electric energy production are the origins of the energy constraints, and are defined below:

(i) The flow through the turbines should meet energy generation demand, i.e.,

$$E_{i,j,t} = Cf * (O_{i,j,t} + OE_{i,j,t}^{q,j_g} + O_{i,j,t}^{m}) * He_{i,j,t} * e_{i,j} * h_{i,j,t}$$
For all i, j and t (5.3.11.1)

where

| E <sub>i, j, 1</sub>                   | Total energy generated from hydropower plant at site i, in sub-basin j, in time t                          |
|----------------------------------------|------------------------------------------------------------------------------------------------------------|
| Cr                                     | Conversion factor from m cm/month to mw-h                                                                  |
| O <sub>i,j,1</sub>                     | Total release from site i, in sub-basin j, in time t                                                       |
| ΟΕ <sup>q, j</sup> <sub>ε</sub> , j, ρ | Export from site i, in sub-basin j, to irrigation area p, upstream of site q, in importing sub-basin $j_E$ |
| $O_{i,j,t}^m$                          | Mandatory releases to downstream natural channel from site i, in sub-<br>basin j, in time t                |
| He i, j, t                             | Average storage head at dam, for site i, in sub-basin j, in time t                                         |
| e <sub>i, j</sub>                      | Turbine and generator efficiency of hydropower plant at site i, in sub-<br>basin j                         |
| h <sub>i,j,t</sub>                     | Number of hours in the period t at dam for site i, in sub-basin j, in time t                               |

(ii) Total energy is defined by

$$E_{i,j,t} = \delta_{i,j,t} * E_{i,j} + \overline{E}_{i,j,t}$$
 For all i, j and t (5.3.11.2)

| E i. j. t                         | Total energy generated from hydropower plant at site i, in sub-basin j, in time t |
|-----------------------------------|-----------------------------------------------------------------------------------|
| $\delta_{i,j,t}$                  | Energy requirement in percentage at site i in sub-basin j in time t               |
| E <sub>i,j</sub>                  | Annual energy generation target for site i, in sub-basin j                        |
| $\overline{\overline{E}}_{i,j,t}$ | Secondary energy generated at dam in mw-h for site i, in sub-basin j, in time t   |

(iii) Energy production is also limited by the percent of time that the plant will produce power specified by the load factor, i.e.,

$$E_{i,j,t} = \alpha_{i,j,t} * H_{i,j} * h_{i,j,t}$$
 For all i, j and t (5.3.11.3)

| $E_{i,j,t}$        | Total energy generated from hydropower plant at site i, in sub-basin j, in time t                                        |
|--------------------|--------------------------------------------------------------------------------------------------------------------------|
| $H_{i,j}$          | Hydropower capacity at dam for site i, in sub-basin j                                                                    |
| $\alpha_{i,j,t}$   | Load factor at each hydropower site i, in sub-basin j, in time t, for each period t is an indicator of the energy demand |
| h <sub>i,j,1</sub> | Number of hours in the period t at dam for site i, in sub-basin j, in time t                                             |

# COMPUTATION OF INPUT DATA FOR LINEAR PROGRAMMING MODEL

#### 6.1 GENERAL

The Cauvery river basin has been divided into sixteen sub-basins having fifteen major irrigation projects as discussed in Chapter 3. The computation of input data for linear programming model, i.e., distribution of upstream and downstream irrigation and water supply requirements from medium and minor irrigation projects to project sites, distribution of ground water at project level, estimation of various co-efficients, estimation of flows of various annual water year dependabilities have been worked in this chapter. These computed values are used in the computation for LP model developed in Chapter 5 for the objective function No.1, i.e., maximization of annual surface and ground water utilization of for irrigation, water supply for domestic use, hydro-power and environmental uses. The notations used in the preparation of a LINDO format for running the model by writing the equations for readily available LINDO software package of 6.1 version, released in August 2001, by LINDO Systems, Inc, 1415 North Dayton St. Chicago, IL, U.S.A., and the water demands for various purposes as per NWDA also are given in this chapter.

The various basic data required for preparation of water balance studies for all the sixteen sub-basins in Cauvery river basin and Cauvery river basin as a whole, and for running the linear programming, mathematical model for Cauvery river basin, are collected from the various reports of National Water Development Agency (NWDA), New Delhi and Central Ground Water Board (CGWB), Faridabad, under the Ministry of Water Resources, Government of India. The data is computed in the required form and format to feed the data for running the model in LINDO software package of version 6.1 released in August 2001, for solving the problem.

The pertinent features of the various major projects in Cauvery river basin for all sixteen sub-basins are given in Table 6.1.

The data available from various reports of NWDA and the publications of CGWB are used for computation of the data for running the LP model to get the required results to achieve the designed objective functions. Sometimes the data available are not in the form, suitable for model computation. The data to be used are usually estimated from the available data to conform to the model requirements before use.

The following data are computed and described as below.

- (i) Distribution of upstream and downstream irrigation and water supply requirements from medium and minor irrigation projects to project sites,
- (ii) Distribution of Ground water,
- (iii) Estimation of various co-efficients, and
- (iv) Estimation of flows of various annual water year dependabilities.

# 6.2 DISTRIBUTION OF UPSTREAM AND DOWNSTREAM IRRIGATION AND WATER SUPPLY REQUIREMENTS FROM MEDIUM AND MINOR IRRIGATION PROJECTS TO PROJECT SITES

The locations of medium irrigation schemes in the catchments area of major irrigation projects are available but the details of locations for minor irrigation schemes in the catchment area of major irrigation projects are not available, hence the utilization

Table 6.1: Pertinent Features of Dam Sites in Cauvery River Basin

of minor irrigation schemes was distributed on the proportion of catchment area basis of the major projects.

But the model results were not satisfactory, in the sense that the system targets met were much away from the plan proposals. Hence the minor irrigation utilization of the sub-basin was redistributed as per the state wise utilization of minor irrigation schemes data available in NWDA reports of Cauvery basin, in the proportion of catchment areas of the respective state wise projects. Hence the LP model results are improved.

The computation made for the distribution of minor irrigation schemes and medium irrigation project's contribution to the water requirements for rural human and live stock water supply, irrigation, and ground water; upstream and downstream of the major irrigation project are computed as follows:

Let,

Cai = Catchment area of the major irrigation project site i,

Ea Sum of net or gross catchment area of all the major irrigation projects, depending upon series or parallel major irrigation projects, in the subbasin j,

Iu<sup>m</sup><sub>i,j</sub> = Upstream rural water supply requirements at project level i, in sub-basin j,

Iu'<sub>i,j</sub> = Upstream irrigation water requirements by minor and medium irrigation projects,

 $RWT_j$  = Total rural water supply requirements of sub-basin,

RW<sub>i,j</sub> = Upstream rural water requirements at project level (M),

RWMI = Upstream rural water supply requirements at project level by minor projects (Q),

- RWMD = Upstream rural water supply requirements at project level by medium projects,
- RWMIH = Upstream rural human water requirements from minor irrigation projects,
- RWMIL = Upstream live stock water requirements from minor irrigation projects,
- RWMD = Upstream rural human water supply requirements from medium irrigation projects,
- RWMDL = Upstream live stock water supply requirements from medium irrigation projects.
- (1) Upstream rural water supply requirements at project level (M):
  - RW = [Intervening catchment area of project / Total catchment area of sub-basin] \* [Total annual rural water supply requirements of sub-basin],

$$= [Ca_{i} / Ca^{T}] * RWT$$

$$= Iu_{i,j}^{m}.$$

- (2) Upstream irrigation water requirements from minor irrigation at project level (P):
  - P = [Intervening catchment area of project] / [Total catchment area of sub-basin \*

    Total minor irrigation requirements of sub-basin].
- (3) Upstream rural water supply requirements at project level by minor projects (Q):
  - RWMI = [Upstream irrigation water requirements from minor irrigation at project level\* Upstream rural water supply requirements at project level] / [Upstream irrigation water requirements by minor irrigation at project level + Upstream irrigation water requirements by medium irrigation at project level]

RWMI = 
$$[P * M] / Iu_{i,j}^r$$
  
=  $[P * Iu_{i,j}^m] / Iu_{i,j}^r$ 

where M = Upstream rural water supply requirements at project level $= <math>[C_a, K_a]^* RWMIL]$ 

- (4) Upstream rural water supply requirements at project level by medium projects (R):
  - RWMD = [Upstream irrigation water requirements from medium irrigation at project level \* Upstream rural water supply requirements at project level] / [Upstream irrigation water requirements by minor irrigation at project level + Upstream irrigation water requirements by medium irrigation at project level]
  - RWMD = [Upstream irrigation water requirement from medium irrigation at project level \* Iu<sup>m</sup><sub>i,j</sub>] / Iu<sup>r</sup><sub>i,j</sub>
- (5) Upstream human population at project level:
  - = [Intervening catchment area of project / Total catchment area of subbasin] \* [Human population of the sub-basin].
- (6) Upstream lives stock population at project level:
  - = [Intervening catchment area of project / Total catchment area of subbasin] \* [Live stock population of the sub-basin].
- (7) Upstream rural human water supply requirements from minor irrigation projects: (RWMIH):
  - RWMIH = [Upstream rural water supply requirements from minor irrigation at project level \* Upstream human population at project level]/

    [Upstream human population at project level + Upstream live stock population at project level].
- (8) Upstream live stock water supply requirements from minor irrigation projects (RWMIL):

- RWMIL = [Upstream rural water supply requirements from minor irrigation at project level \* Upstream live stock population at project level] / [Upstream human population at project level + Upstream live stock population at project level].
- (9) Upstream human rural water supply requirements from medium irrigation projects (RWMDH):
  - (RWMDH) = [Upstream rural water supply requirements from medium irrigation at project level \* Upstream human population at project level] / [Upstream human population at project level + Upstream live stock population at project level].
- (10) Upstream live stock water supply requirements from medium irrigation projects (RWMDL):
  - RWMDL = [Upstream rural water supply requirements from medium irrigation at project level \* Upstream live stock population at project level] / [Upstream human population at project level + Upstream live stock population at project level].
- (11) Total rural human water supply requirement at project level (RWMIH + RWMDH):
  - RWMIH + RWMDH = [Upstream human rural water supply requirements from minor irrigation projects + Upstream human rural water supply requirements from medium irrigation projects].
- (12) Total lives stock water requirement at project level (RWMIL + RWMDL):
  - (RWMIL + RWMDL) = [Upstream live stock water requirements from minor irrigation projects + Upstream live stock water supply requirements from medium irrigation projects].

(13) Industrial and urban water supply for each major irrigation project to be distributed as: the intervening net or gross catchment area of the major project depending upon series or parallel projects in the sub-basin / total catchment area of the sub-basin multiplied by total Industrial / urban water requirement of the sub-basin.

### 6.3 GROUND WATER COMPUTATIONS AT PROJECT LEVEL

The total ground water available in the sub-basin is distributed at project level and the ground water available at each project level is distributed as upstream and downstream ground water as below:

Total ground water in the sub-basin =

=  $\Sigma$  Upstream ground water at project level

+ Σ Downstream ground water at project level

Total ground water at project level = Upstream and downstream ground water at project level.

### 6.3.1 Upstream Ground Water at Project Level =

= [Intervening gross or net catchment area of the major project / Total catchment of the sub-basin] \* [Total ground water available in the sub-basin].

### 6.3.2 Downstream Ground Water at Project Level

= [Cultivable command area of the major project / Total catchment of the sub-basin] \* [Total ground water available in the sub-basin].

If, the projects are in parallel, then, Catchment area = Gross catchment area of the major project, and, If, the projects are in series, then, Catchment area = Net catchment area of the major project.

The values of the distribution of upstream and downstream irrigation and water supply demands, and ground water are computed and given in the Table 6.2.

Table 6.2: Upstream and Downstream Annual Irrigation and Water Supply Requirements of All Major Projects in Cauvery River Basin

#### 6.4 ESTIMATION OF VARIOUS COEFFICIENTS

The following coefficients are computed as follows:

### 6.4.1 Reservoir Evaporation Coefficient $(K'_{i,i,t})$

Firstly, the LP model for every individual projects were run without considering evaporation losses from the reservoirs and storages of each reservoirs were obtained, by adding of the dead storages of each sites the gross storages are calculated, by knowing the area of submergence at full reservoir level. The reservoir operation table (working table) was prepared for each reservoir using average monthly flows and considering evaporation losses. From the results,  $K_{i,j,t}$  was calculated as:

$$K'_{i,j,t} = 1 + (El_{i,j,t}/S_{i,j,t})$$

The values of  $El_{i,j,t}$  and  $S_{i,j,t}$  were taken from the results of LP model running on LINDO software for each site, i. Reservoir operation tables (working table) was prepared for each reservoir using average monthly flows and considering evaporation losses from the results. The values of  $K_{i,j,t}$  calculated for all the fifteen sites in Cauvery river basin are presented in Table 6.3.

### 6.4.2 Percent of Annual Irrigation (K<sub>i.i.t</sub>)

The values of  $K_{i,j,t}$  are computed from monthly crop requirements of each crop. This is the ratio of monthly and annual crop water requirements, such that  $\frac{12}{\sum_{t=1}^{K} K_{i,j,t}} = 1.$ 

Computation of K<sub>i,j,t</sub> is given below:

$$SUM_{i,j}(t) = \sum_{k=1}^{NCI^{i, j}} W_{i, j, t}^{k} * A_{i, j}^{k}$$
 for all i,j, and t (6.1)

$$TSUM_{i,j} = \sum_{t=1}^{12} SUM_{i,j}(t)$$
 for all i and j, (6.2)

Table 6.3: Estimated Monthly Reservoir Evaporation Coefficients at Cauvery River Basin from All Major Projects

$$K_{i, i, t} = SUM_{i, j}(t) / TSUM_{i, t}$$
 for all i, j, and t (6.3)

The computed values of K<sub>i,i,t</sub> are given in Table 6.4.

### 6.4.3 Percent of Return Flow to River from Irrigation (Kij,t)

The percent of return flow to river from irrigation was taken as 10 to 20 percent depending on the age of the reservoir.

### 6.4.4 Percent of Upstream Annual Water Use for Irrigation ( $\alpha_{i,j,t}$ )

The percent of upstream annual water use for irrigation is the percent ratio of monthly and annual crop water requirement. The computed values are same as given in Tables 6.4.

## 6.4.5 Percent of Return Flow to River from Upstream Water Use for Irrigation $(\alpha_{i,i,t})$

The percent of return flow to river from upstream water use for irrigation is taken as 10 to 20 percent depending on the age of the reservoir.

### 6.4.6 Percent of Upstream Annual Water Supply (β<sub>i, j, t</sub>)

The percent of upstream annual water supply use are computed as:

 $\beta_{i,j,t}$  = (Number of days in a month/ number of days in a year (365 days)\*100.

### 6.4.7 Percent of Return Flow to River from Upstream Water Use for Water Supply $(\beta_{i,j,t}^n)$

The percent of return flow to river from upstream water use for water supply is taken as 80 percent.

6.4.8 Percent of Annual Surface Water Requirement for Urban Domestic Water Use  $(\phi_{i,\ j}^{U^*})$ 

The percent of annual surface water requirement for urban domestic water use is taken as 100 percent.

6.4.9 Percent of Annual Ground Water Requirement for Urban Domestic Water Use  $(\varphi_{i,\ j}^{U^s})$ 

The percent of annual ground water requirement for urban domestic water use is taken as 0 percent.

6.4.10 Percent of Annual Surface Water Requirement for Rural Human Population Domestic Use (  $\phi_{i,\ j}^{RH'}$  )

The percent of annual surface water requirement for rural human population domestic use is taken as 50 percent.

6.4.11 Percent of Annual Ground Water Requirement for Rural Human Population Domestic Use  $(\phi_{i,j}^{RH^g})$ 

The percent of annual ground water requirement for rural human population domestic use is taken as 50 percent.

6.4.12 Percent of Annual Surface Water Requirement for Live Stock Use (  $\phi_{i,j}^{RL^s}$  )

The percent of annual surface water requirement for live stock use is taken as 0 percent.

6.4.13 Percent of Annual Ground Water Requirement for Live Stock Use ( $\varphi_{i,}^{RL_{i,j}^g}$ )

The percent of annual ground water requirement for live stock use is taken as 100 percent.

### 6.4.14 Percent of Annual Surface Water Requirement for Industrial Use $(\varphi_{i,j}^{I'})$

The percent of annual surface water requirement for industrial use is taken as 100 percent.

### 6.4.15 Percent of Annual Ground Water Requirement for Industrial Use $(\varphi_{i,j}^{Ig})$

The percent of annual ground water requirement for industrial use is taken as 0 percent.

### 6.4.16 Percent of Annual Water Use for Urban and Industrial $(\xi_{i,j,t})$

The percent of annual water use for urban domestic and industrial use is taken as 100 percent from surface water and zero percent from ground water.

### 6.4.17 Percent of Import to a Site $(\psi_{i,j,t}^{q,j_i})$

The percent of import to the importing site is computed in the ratio of the monthly irrigation requirements of the importing site to the total annual irrigation requirements of the importing site.

### 6.4.18 Percent of Export to Site ( $(\omega_{i_1,i_1,1}^{q_i,j_1})$ )

The percent of export from site i is computed in the ratio of monthly irrigation requirements of the importing site to the total annual irrigation requirements of the importing site.

### 6.5 ESTIMATION OF FLOWS OF VARIOUS ANNUAL WATER YEAR DEPENDABILITIES

The computation of water year annual dependable flows for the years representing a normal, dry and wet years were calculated using flow-duration analysis of annual (water year) flows. These were (i) 75% water year annual

dependable flow representing a water year under normal conditions, (ii) 90% water year annual dependable flow representing a water deficit year, (iii) 100% (lowest flow) water year annual dependable flow representing a critical water deficit year, and (iv) 50% water year annual dependable annual flow representing a water surplus year. The model constraints were written for NT = 12 months because the computations were done over one year interval only.

### 6.5.1 Estimation of Inflows at Project Levels

The inflow values for each reservoir in the Cauvery river basin are computed by using the rainfall data available in the various NWDA reports of compilation of basic data for all fifteen reservoirs in Cauvery river basin. The annual dependable yield of the reservoir is distributed in the proportion of the monthly rainfall data of the nearest rain gauge station to the reservoir. In the absence of catchment maps, this was adopted.

Inflows in the individual major projects in the Kabini and Upper Cauvery sub-basins are computed by considering the monthly/annual average rainfall values for the 75 percent annual water year dependable flow of the sub-basin from which the annual yield is calculated for water balance studies, from the nearest rain gauge station to that major project.

For the Krishnarajsagar (KRS) major project in the Upper Cauvery sub-basin, the inflow is computed by deducting the sum of inflows in the major project in sub-basin from total inflow of the sub-basin as this project is at the end or terminal point of the sub-basin.

For Chinnar, Bhavani and Amaravathi major projects the inflows are taken as given in these respective project reports as each of them is single major project in its

respective sub-basins.

The computed 50%, 75%. 90% and 100% monthly and annual water year dependable flows are given in Table 6.5 (a) to Table 6.5 (d).

### 6.6 THE LP LINDO FORMAT

The LP LINDO format is prepared for running the model by writing the equations in the required format for readily available LINDO software package of 6.1 version released in August 2001, by LINDO Systems, Inc., 1415 North Dayton St. Chicago, IL, U.S.A., and is given in appendix - I. The notations used in the LP model are given as below.

The nomenclature of the variables for writing the equations for running the model on LINDO software package was done by using first single letter of the name of a project site, first two letters of the name of a sub-basin and maximum first five letters of name of a variable, because the LINDO software package version 6.1 (August 2001) allows maximum eight letters for the nomenclature of a variable for running the model to obtain a feasible solution of the problem by running the model on it.

The projectwise and variablewise notations used for running the model on the LINDO software package are given as below in Tables 6.6.1 and 6.6.2, respectively.

Table 6.5 (a): Annual Flows with Different Dependabilities at Various Sites in Upper Cauvery Sub-basin

#### 6.7 THE VARIOUS DEMANDS AS PER NWDA

The water demands for various purposes as per NWDA are given in Table 6.7.

# 6.8 COMPUTATION OF WATER REQUIREMENT TO MEET THE MINIMUM FOOD REQUIREMENTS OF THE AGRICULTURAL POPULATION IN THE COMMAND OF MAJOR RESERVOIRS

### 6.8.1 Estimation of Agriculture Population

The sub-basinwise rural and urban population within the Cauvery river basin is obtained from the various reports of compilation of basic data and preliminary water balance studies of NWDA. The rural and urban population for the year 1981 taken from the census figures is projected for the year 2050. The year 2050 is chosen as the water balance studies are carried out for the year 2050, after which a reassessment may be done. The total agricultural population at each major project level is computed in the proportion of the command area of each major project lying in the sub-basin for all the fifteen major reservoirs having irrigation component in sub-basins as per their culturable command areas. The computation of the agricultural population for all the fifteen major reservoirs in the basin having irrigation component in shown in Table 6.8.2.

### 6.8.2 Minimum Food Requirements

Nutritional requirements (proteins and calories) per capita per day: The daily dietary allowances of proteins and calories for male and female in different age groups are obtained from Ghei and Ghei (1973) and Thaper (1981). The daily dietary allowances are shown in Table 6.8.1.

The average per day requirement of Proteins and calories for males and females are worked out separately by using the weighted average method. The male female ratio is used to obtain the weighted average of protein and calorie requirement on a per capita per day basis. The male female ratio of 931 females per 1000 males for Cauvery river basin gives a percentage of 53.45% males and 46.55% females. The computations for obtaining per capita per day requirement of calorie and protein are shown below:

### A) Calorie requirement

(i) Weighted average of calorie requirement for males

= 2524.90 calorie units

(ii) Weighted average of calorie requirement for females

The combined weighted average calorie requirement per capita per day for the whole population shall be

- B) Protein requirement
  - (i) Weighted average of protein requirement for males

(i) Weighted average of protein requirement for females

The combined weighted average calorie requirement per capita per day for the whole population shall be:

$$= [(53.45 * 63.78) + (46.55 * 58.33)] / 100$$

The calculations done for all the remaining projects being similar except for minor difference in the male female ratio (number of females per 1000 males), are not shown here.

Crop produce requirement per capita per day:

The protein and calorie content of different crops as obtained from Ghei and Ghei (1973) and Thaper (1981) are shown in Table 6.8.4.

Table 6.8.4: Protein and Calorie Content of Different Crops

| Crop           | Proteins (Grams/Kilogram) | Calories (Units/Kilograms) |

The cropping patterns suggested by NWDA are considered, and taking into account the average food habits of people, the per capita per day crop produce for each food crop is decided so as to fulfill the per capita per day nutritional requirement (proteins and calories) of the population. The calculations are shown in Table 6.8.5(a). The calculated per capita per day requirements of crops should give a higher per capita per day nutritional (protein and calorie) content than the per capita per day nutritional requirement obtained as per the daily dietary allowances. Computation of crop production to meet the minimum food requirement of agricultural population is given in Table 6.8.5(b).

### 6.8.3 Water Requirements to Meet the Minimum Food Requirements

The average yield of crops per unit area (hectare) is obtained from the data available in the Agricultural Statistics by Narmada Planning group (1989). As Narmada river basin being near to Cauvery river basin the easily available data is used. The crop coefficients (depicting the proportion of crop produce to the yield of crop) are considered for crops such as paddy and groundnut to decide the crop produce (on an average one quintal of paddy gives 66.0 Kilograms of milled rice, and one quintal of groundnut gives 70Kilograms of groundnut seed). The area of a crop to be brought under cultivation for meeting the crop produce requirement of each crop is worked out on an annual basis for the agricultural population in the command of each major reservoir. The average field water requirements (depth in m) of individual crops in the respective sub-basins are used to work out the annual water requirement for each crop. The summation of all the crops gives the annual field water requirements sufficient to fulfill the minimum food requirements of the agricultural population in the command area of each major reservoir. The computed values are shown in Table 6.8.6.

### COMPUTATION AND RESULTS OF LINEAR PROGRAMMING MODEL

### 7.1 GENERAL

A linear programming model for Cauvery river basin has been developed in Chapter 5. This model has constraints based on continuity equation of reservoir sites, total release from the reservoir, projectwise and sub-basinwise irrigation, domestic water supply for rural human population, live stock and urban population from surface and ground water, industrial use, hydropower, and environmental use, exports and imports from irrigation projects, regeneration from irrigation, domestic and industrial water use, availability of surface and ground water, land use and crop water requirements, hydro electric energy and some design constraints according to the interim award of Cauvery Water Dispute Tribunal (CWDT), about the water sharing among the co-basin states, i.e., Karnataka, Kerala, Tamilnadu and Pondicherry. The characteristics of the Cauvery river system and interim award of CWDT, under taken for this study and the data required for this purpose are given in Chapter 3.

The data such as inflows to reservoirs and sub-basins, capacities of reservoirs and canals, monthly water requirements and time period for each crop, projectwise cultivable command area (CCA), percentage CCA of each crop for each project and each sub-basin, availability of surface water were collected from various technical reports of National Water Development Agency (NWDA), New Delhi, a autonomous body under the Ministry of Water Resources, Government of India as given in the list

of references and the data about ground water availability was collected from the report of Ground Water Resources of India (1995), published by Central Ground Water Board, under the Ministry of Water Resources, Government of India, Faridabad. Some additional constraints were added in the model, in terms of sharing of river water and limiting its use under numerous techno-economic and management constraints pertaining to CWDT, and the detailed modeling of many more site specific hydrological/physical constraints of the problem. In addition certain data have been computed from available information in Chapter-6. It includes the computation of various coefficients such as reservoir evaporation coefficients, computation of percent annual water use for irrigation and water supply from each site and sub-basin, monthly percent of export and imports for each project and sub-basin, estimation of flows of various annual water year dependabilities and computation of ground water availability for each project and sub-basin from the district wise ground water data available from publication, ground water resources of India published by Central Ground Water Board (CGWB) under the Ministry of Water Resources, Government of India, Faridabad, (1995).

The mathematical formulation of linear programming model has 3650 constraints. Out of these 3578 are equalities, 60 are of less than or equal to type, and 12 are greater than or equal to type. The number of unknown decision variables are 1000 which includes variables relating to crop area, reservoir storage, reservoir releases and spills, diversion of water for irrigation and water supply, capacity of reservoirs, upstream and downstream annual irrigation and water supply, ground water use. Models of many practical problems under investigation in water resources development programmes may be generally solved on personal computers using

simplex-based algorithms.

In this research work the readily available LINDO package of 6.1 version released in August 2001, by LINDO Systems, Inc. 1415 North Dayton St. Chicago, IL, USA, having the maximum capacity of 4000 constraints and 8000 variables with 100 integer variables and 2000000 non zeros, was used to solve the LP model problem, as there are many constraints and variables to handle such a big problem.

#### 7.2 COMPUTATION OF LP MODEL

The computations were carried out for various water year dependable flows representing a normal, dry and wet years. These were calculated using flow-duration analysis of annual (water year) flows. These were: (i) 75% water year dependable flow representing a water year for water sharing under normal condition as per the interim award of Cauvery Water Dispute Tribunal (CWDT), (ii) 90% water year dependable flow representing a water deficit year, (iii) 100% water year dependable flow resenting a critical water deficit year, and (iv) 50% water year dependable flow representing a water surplus year. The model constraints were written for NT = 12 months because the computations were done over one year interval only.

In the LP model, constraints were written only for one year. Computation of LP model has been done on the basis of monthly flows, using 50%, 75%, 90% and 100% water year dependable flows. The reservoir storage at the end of year (June to May) was taken to be same as at the beginning of the same year, i.e.,  $S_{i, 12} = S_{i, 0}$ , assuming no over the year carry over storages in reservoirs. The return flows from irrigation and water supply and industrial water uses were taken as 10% to 20%, 80% and 80% respectively, as per norms of NWDA.

All the values of  $I_{i,t}$ ,  $P_{i,t}$  and  $O_{i,j,t}^{m}$  in equation (3) were taken as zero. Based on the CWDT some additional constraints on various design variables were added in terms of either upper bounds or limiting their values. In this chapter, we briefly review as to how far we have succeeded in this effort, i.e., an attempt made to add additional constraints in the model as per the CWDT award and analyzing the results by applying the LP model developed in Chapter 5 to Cauvery river basin.

As the first objective function of the problem is for, maximization of annual water utilization for irrigation, water supply, industrial, hydropower and environmental uses from surface water and ground water, the model was first run for 75% water year dependable flow. The model was run for each project in parallel separately, without consideration of the contribution from the upstream project within a sub-basin, and then it was combined at a sub-basin level with consideration of the contribution of inflows from the projects in series and for remaining area.

In the Upper Cauvery sub-basin, there are five irrigation projects, in Kabini sub-basin, there are seven irrigation projects and in Chinnar, Bhavani and Amaravathi sub-basins there is one project in each sub-basin. In other sub-basins there are no major irrigation projects. For such sub-basin, having no major irrigation project, the LP model is run as a single model for that sub-basin as a whole at the end point of the sub-basin. Then combining all the models for each sub-basin, a single model for Cauvery river basin as a whole is obtained with consideration of the sub-basins in parallel or in series for contribution of inflows from upper irrigation projects and the upper sub-basins in series.

The computational methodology for LP model run for the whole Cauvery river system is explained below, with a simple example of Upper Cauvery sub-basin with details of what exactly is the configuration for which LP model is run. The input data where exact possible mentioning the notations used in LP model is given in Chapter 6. The list of output decision variables, resulting from model are given in Table 6.6.2.

The methodology adopted while running the LP model at a project level, a sub-asin level and Cauvery basin as a whole level as follows:

- 1. Select the upper most sub-basin, i.e., Upper Cauvery in the Cauvery basin.
- Analyze each major reservoir one-by-one in Upper Cauvery sub-basin Fig.3.3.1, as follows:
  - (a) Analyze Yagachi as an independent reservoir.
  - (b) (i) Analyze downstream Hemavathi as an independent reservoir without any regulated contribution from upstream Yagachi reservoir.
    - (ii) Analyze downstream Hemavathi reservoir in series with upstream Yagachi reservoir with regulated contribution Yagachi.
  - (c) Analyze Harangi as an independent reservoir.
  - (d) Analyze Cauvery as an independent reservoir.
  - (e) (i) Analyze downstream KRS as an independent reservoir without any regulated contribution from upstream reservoirs mentioned as above.
    - (ii) Analyze downstream KRS in series with upstream reservoirs with regulated contributions from upstream Hemavathi, Harangi and Cauvery reservoirs. Thus analyzing the entire Upper Cauvery sub-basin as as an one entity.
- (3) Like in step-2, all the sub-basins having major reservoirs are first analyzed as individual sub-basins.
- (4) Whole sub-basin not having any major reservoir is analyzed assuming that all the water is being utilized at the end of the sub-basin.
- (5) Lastly, all the 16 sub-basins are combined together and the entire Cauvery basin is analyzed as a whole gasin wide would sun was made fer entire Cauvery basin.

  According to the interim award of Cauvery Water Dispute Tribunal (CWDT).

205 TMC ft (5800 MCM) of water is to be released to Tamilnadu state at Mettur, the 13<sup>th</sup> reservoir in the 8<sup>th</sup> sub-basin from the upstream reservoirs in Karnataka state, and its monthwise releases are also maintained in the interim award. Firstly, to run the

model the annual export of water from Mettur was taken, equal to the CWDT value of 5800 MCM through Mettur reservoir and monthly exports were taken as per the monthly quantities maintained in CWDT. Then the model was run by changing the export quantities from Mettur to the sub-basins below Metter as less than and greater than the 5800 MCM, to check the effect on upstream and downstream irrigation and water supply in the sub-basins above and below of Mettur reservoir. The export quantities taken for running the model were 4200MCM, 6200 MCM and the highest maximum possible values for various dependabilities flows were found out as 6700 MCM, 6900MCM, 7200 MCM and 7800 MCM in case of 100%, 90%, 75% and 50% water year dependable flows, respectively. Hence the upper bound or limiting the values of monthly releases were taken in the proportion of the monthly quantities of export maintained in CWDT. These include upper bound and equal values on monthly irrigation diversions through Mettur, equal to bounds on capacities of reservoirs and canals, and mixed bounds on ground water availability and uses, annual downstream and upstream irrigation, domestic (rural, urban and live stock population water requirements) and industrial water uses, exports. Then the model was run on the basis of monthly flows, of 50%, 90% and 100% water year dependabilities. The results of LP model for Cauvery river basin for 75%, 50%, 90%, and 100% water year dependable flows are presented in this chapter. While running the LP model for Cauvery river basin, the following points are observed and the steps taken while running the model AS UR LEGAM are given as below.

### 7.2.1 Sample Computational Steps (for Kabini Sub-Basin)

The following steps are taken while running the model for Kabini sub-basin with all major projects and remaining area for improvements of objective function values so as to make the system efficient for irrigation and water supply use

Step (1): The locations of medium irrigation schemes in the catchments area of major projects are available but the details of locations for minor irrigation schemes in the

catchment area of major projects are not available hence the utilization of minor irrigation schemes was distributed on the proportion of catchment area basis of the major projects.

But the model results were not satisfactory in the sense that the system targets met were much away from the plan proposals. Hence the minor irrigation utilization of the sub-basin was redistributed as per the state wise utilization of minor irrigation schemes data available in NWDA reports of Cauvery basin, in the proportion of catchment areas of the respective state wise projects.

Step (2): (a) The inflow data for the major projects were taken from the salient features of the respective major projects, as per the yield availability data at the time of preparation of project reports by the respective state governments and was distributed in the proportion of monthly inflows of water balance studies of sub-basin with and without ground water, but the total sum of individual projects was not tallying to the total water available in water balance studies of the sub-basin.

Step (2): (b) Then the rainfall data is taken from the nearest rain-gauge stations of the respective major projects of 75% water year dependable flow and multiplied by the catchment area of the respective projects for getting the monthwise run-off or monthwise inflows available at the respective major projects. The data was taken from the basic data booklet of the Kabini sub-basin prepared by NWDA.

Inflows for the remaining area is kept equal to the water demands of urban and industrial water requirements for remaining area and balance inflows (i.e. in flow calculated in step 2(a)- Urban and industrial water requirements) from the remaining area is distributed to upstream major projects in the proportion of the catchment areas of the upstream major projects and added to flows in step 2(a)

Step (3): Initially satisfactory results were not obtained as the model was utilizing water for irrigation, only from ground water and not from surface water. Further modifications were made while running the model was that the spills for Banasursagar project were kept equal to zero for each month in Banasursagar project. Then the results were improved.

Case (1): The proposed export quantity of 495.50 MCM was reduced to 400 MCM from the ongoing Manathvady multipurpose project to get a feasible solution from the model.

Case (2): Flow pattern was changed and was taken as per the average month wise inflows of Manathvady and Banasursagar, keeping the annual rainfall values the same.

Case (3): Number of trials were made while running the model by changing the storage capacities of Nugu and Sagar Doddakere project for various alternatives but values of the objective functions were not improved hence,

Case (4): Further modification for model was made by increasing the storage capacity of Kabini project-I from the existing storage capacity of 453 MCM to 610 MCM, the value of objective function was increased from 1464.27 MCM to 1683.60 MCM, with a very good and satisfactory results for utilization of water for irrigation and water supply from all the major projects in the Kabini sub-basin. But for final results of the model the capacity of the Kabini project is kept as per its designed capacity and the final results of the LP model are obtained and presented in this chapter.

### Assumptions:

The following observations were found while running the optimization LP model for the Cauvery river basin.

- (1) The changes were done while running the model that the exports from the various major irrigation project / sub-basins were taken in the proportion of monthly irrigation requirements of the importing sub-basins instead of exports in the monthly water availability in the exporting sub-basins
- (2) The main Cauvery river bifurcates at Grand anicut into Upper Coleroon and Cauvery Delta, the total discharge of river is considered as 60% and 40% to Cauvery delta and Upper Coleroon sub-basins respectively.
- (3) Model was checked by running as per the monthly releases as per the interim award of Cauvery Water Dispute Tribunal and it also was checked for the

values greater than and less than the values of tribunal award and it was also observed that what is the effect on upstream and downstream of the Mettur dam, to fulfill the various requirements of irrigation and water supply to the subbasins below Mettur reservoir.

- (4) The environmental requirements were considered as 1% of the monthly inflows in the sub-basins and regeneration from irrigation was considered as 10% to 20% as per age consideration of the dams, of net irrigation requirements at field level and 80% from domestic and industrial water requirements.
- (5) Ground water utilization was considered as 100% and the available ground water was calculated from data collected from the Central Ground Water Board (CGWB), Faridabad, India. It was calculated in proportionate area basis of the districts in the catchments of each sub-basin.
- (6) For 75% water year dependable flows, the monthly distribution of export from Mettur for 4200 MCM annual value was take as less than or equal to the monthly values of tribunal award but in the results the values in the month of June, January, February and April were taking equal to zero hence 4200 MCM value was distributed in the proportion of, the values of monthly releases as per interim award of Cauvery Water Dispute Tribunal's Award (CWDT).
- (7) For 75% water year yield for 4200 MCM, 5800 MCM, 6200 MCM and 7200 MCM export from Mettur to the sub-basins below Mettur reservoir, in the proportion of, the values of monthly releases as per interim award of Cauvery Water Dispute Tribunal's Award (CWDT).
- (8) Changes observed in the values of utilization in case of 7200 MCM:
- (a) Above Mettur: In case of Nugu reservoir down stream irrigation changes from 137 to 440 MCM.
  - (b) Below Mettur: In case of Noyil sub-basin utilization for irrigation is equal to zero.

The results obtained by running the LP model for Cauvery basin as a whole with 50%, 75%, 90% and 100% water year dependable flows with various export quantities of 4200 MCM, 5800 MCM, 6200 MCM, 6700 MCM, 6900 MCM and 7200 MCM, are presented in Tables 7.1.1 to 7.1.4, respectively.

### 7.3 RESULTS OF LP MODEL FOR 75% WATER YEAR DEPENDABLE FLOW (A NORMAL YEAR) (FOR MAXIMIZATION OF WATER UTILIZATION)

Based on the steps as given in Section 7.2.1, the model was first run by using 75% water year dependable flow. The results of LP model for Cauvery river basin as a whole are presented in Tables 7.1.1(a) to 7.1.1(d). The results of LP model for the values of other design variables and exporting quantity of 4200 MCM, 5800 MCM, 6200 MCM, and 7200 MCM, from Mettur reservoir to the downstream sub-basins below Mettur reservoir, respectively, are presented in Tables 7.1.1(a), 7.1.1(b), 7.1.1(c), and 7.1.1(d). As per the NWDA reports, the maximum designed exports from Mettur reservoir to the sub-basins below the Mettur reservoir and out side of Cauvery basin is found 12712 MCM. But as per LP model, the maximum possible quantity of exports from Mettur to the downstream sub-basins and out of basin, at 75% water year dependable flow was found equal to 7200 MCM. As per NWDA the export value from the Mettur reservoir is given as 12712 MCM, while from the results of LP model the maximum export of 7200 MCM only is possible. The final combined results all the 16 cases of model running with 75%, 90%, 100% and 50% water year dependable flows with 7200 MCM, 6200 MCM, 4200 MCM, and 7800 MCM exports from Mettur reservoir are presented in Table 7.1.5(a) to Table 7.1.5(c).

## 7.4 RESULTS OF LP MODEL FOR 90% WATER YEAR DEPENDABLE FLOW (A WATER DEFICIT YEAR) (FOR MAXIMIZATION OF WATER UTILIZATION)

The model was run for Cauvery river basin for 90% water year dependable flow. The results are presented in Tables 7.1.2(a) to 7.1.2(d). The Tables 7.1.2(a),

7.1.2(b), 7.1.2(c), and 7.1.2(d) for the values of other design variables and exporting quantity of 4200 MCM, 5800 MCM, 6200 MCM, and 6900 MCM from Mettur reservoir to the sub-basins below Mettur reservoir, respectively. As per the NWDA reports, the maximum designed exports from Mettur reservoir to the sub-basins below the Mettur reservoir and out side of Cauvery basin is found 12712 MCM. But as per LP model, the maximum possible quantity of exports from Mettur to the downstream sub-basins and out of basin, at 90% water year dependable flow was found equal to 6900 MCM. The final combined results all the 16 cases of model running with 75%, 90%, 100% and 50% water year dependable flows with 7200 MCM, 6200 MCM, 4200 MCM, and 7800 MCM exports from Mettur reservoir are presented in Table 7.1.5(a) to Table 7.1.5(c).

# 7.5 RESULTS OF LP MODEL FOR 100% WATER YEAR DEPENDABLE FLOW (A CRITICAL WATER DEFICIT YEAR) (FOR MAXIMIZATION OF WATER UTILIZATION)

The model was run for the Cauvery river basin using 100% water year dependable flow. The results are presented in Tables 7.1.3(a) to 7.1.3(d). The Tables 7.1.3(a), 7.1.3(b), 7.1.3(c), and 7.1.3(d) for the values of other design variables and exporting quantity of 4200 MCM, 5800 MCM, 6200 MCM, and 6700 MCM from Mettur reservoir to the downstream sub-basins below Mettur reservoir respectively. As per the NWDA reports, the maximum designed exports from Mettur reservoir to the sub-basins below the Mettur reservoir and out side of Cauvery river basin was found 12712 MCM. But as per LP model, the maximum possible quantity of exports from Mettur to the downstream sub-basins and out of basin, at 100% water year dependable flow was found equal to 6700 MCM. The final combined results all the 16 cases of

model running with 75%, 90%, 100% and 50% water year dependable flows with 7200 MCM, 6200 MCM, 4200 MCM, and 7800 MCM exports from Mettur reservoir are presented in Table 7.1.5(a) to Table 7.1.5(c).

### COMPUTATION 7.6 OF LP MODEL FOR 50% WATER YEAR **DEPENDABLE FLOW SURPLUS** YEAR) (FOR WATER MAXIMIZATION OF WATER UTILIZATION)

The model was run for the Cauvery river basin for 50% water year dependable flow. The results are presented in Tables 7.1.4(a) to 7.1.4(d). The Tables 7.1.4(a), 7.1.4(b), 7.1.4(c), and 7.1.4(d) for the values of other design variables and exporting quantity of 4200 MCM, 5800 MCM, 6200 MCM, and 7800 MCM from Mettur reservoir to the sub-basins below Mettur reservoir, respectively. As per the NWDA reports, the maximum designed exports from Mettur reservoir to the sub-basins below the Mettur reservoir and out side of Cauvery basin was found 12712 MCM. But as per LP model, the maximum possible quantity of exports from Mettur to the downstream sub-basins and out of basin, at 50% water year dependable flow was found equal to 7800 MCM. The final combined results all the 16 cases of model running with 75%, 90%, 100% and 50% water year dependable flows with 7200 MCM, 6200 MCM, 4200 MCM, and 7800 MCM exports from Mettur reservoir are presented in Table 7.1.5(a) to Table 7.1.5(c).

### 7.7 COMPUTATION OF LP MODEL RESULTS WITH CROP CONSIDERATIONS

The LP model was run for the objective functions given by equations 5.2.1-II, 5.2.2, 5.2.3 and 5.2.4, with crops being considered as the decision variables in the model, and the results were obtained for all the objectives for analysis, only for the

75% annual dependable flow. The model runs were made at the individual project/site level, i.e., for all the 15 major projects in the Cauvery river system. The surface water contribution as diversions for irrigation from a reservoir, were made available from the LP model results in Section 7.3. Similarly, the ground water contributions towards irrigation were also obtained from the results in Section 7.3. The model was run for monthly time periods on an annual basis. The results are given in Tables 7.2.1 to 7.2.16.

### 7.8 HYDROPOWER COMPUTATION

The efficiency for energy generation is assumed to be 85% with a hydropower plant factor of 0.6 for all periods in a year. The values of heads for energy generation are computed externally by independent computer programs using the storage elevation curve for each of the multipurpose hydropower reservoirs (i.e., Kabini, Banasurasagar, Mananthvady and Mettur). At variable head sites, average storage head was determined by trial and error.

The nonlinear constraint equation 5.3.11.1 was linearized by assuming an effective head and comparing it with the head specified in the model solution. The values of productive heads are to be substituted externally into the model and are varied after obtaining the solution because of the nonlinear nature of the hydropower generation equation. The parameters used in hydropower energy computations are given in Table 7.3.1. The process was repeated till the reservoir storages obtained are equivalent to the values of heads and the annual system hydropower values get stabilized. The results are given in Tables 7.3.2 to 7.3.5.

Table 7.1.1(a): Results of LP Model for 75% Water Year Annual Dependable Flow (Maximization of Water Utilization)

| Sub-besin                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |          |                       |                   |             |            |          |         |         | Exp          | Export From Mettur Reservoir = 4200 MCM | Mettur R          | eservoir   | = 4200 M   | CM         |               |          |         |         |              |        |

# 8.1 INTRODUCTION

The objective of this research work was to develop a linear programming (LP) model which can be used for planning the development measures of a real life large size transboundary river basin, i.e., for Cauvery river basin, a major river basin in India. The details of the study area are discussed in Chapter 3. Before planning for intra-basin water transfers among the sub-basins lying within a major river basin, water balance of each sub-basin is carried out, with the purpose of identifying water surplus and water deficit sub-basins. In Chapter 4, therefore, the monthly water balance studies on an annual basis, for all the sixteen sub-basins in Cauvery river basin and Cauvery basin as a whole, for the projected population in the Cauvery basin for the scenario 2050 AD were carried out. The water balance studies are done for, with and without the considerations of the ground water availability in the basins. In the water balance study of each sub-basin, the basin was considered as one entity, which lacked the consideration of the influence of the effects of the locations of the various projects involved and the aerial distribution of the runoff in the basin, on the basin's water balance. In order to see the influence of these factors, the LP technique was applied. Therefore, a LP model was developed and applied to the Cauvery river basin. The model can be applied to any river basin planning problem, and is described in Chapter 5. For analysis the 75%, 50%, 90% and 100% water year dependable flows were used. The necessary data needed for the LP model has been computed in Chapter 6. The computed results of LP model are presented in Chapter 7. The analysis of the results is presented in this chapter.

The LP model is basically related to the conjunctive water use development in the river basin. The amount of the ground water resources available is fixed, and was taken as the same in all the model runs. For considering the surface water availability as a resource in the model, firstly, the model was run for 75% water year dependable flow, representing a normal water year for the Cauvery river basin as a whole, with consideration of various water exports from the Mettur reservoir to the down-stream sub-basins below Mettur, then, it was run for the two water shortage years, i.e., the 90% (a water deficit year), and the 100% (a critical water deficit year) water year dependable flows and one water surplus year, i.e., the 50%(a water surplus year) water year dependable flow.

The annual water export quantity to be released from the Mettur reservoir to the sub-basins lying in the downstream reaches of the Cauvery river below Mettur was considered for the following cases: (i) for an amount equal to the interim award of Cauvery Water Dispute Tribunal (CWDTIA), i.e., for 5800 MCM; (ii) for 4200 MCM; (iii) for 6200 MCM; and (iv) for 7200 MCM, 7800 MCM, 6900 MCM and 6700 MCM for the four flows, respectively.

Five objective functions were considered for analyzing various options, mainly related to the irrigation development. The first of them was to maximize, the annual water utilizations from irrigation, and water supply (i.e., domestic and industrial), from major projects, and was subjected to the various constraints on the system related to the availability of surface and ground waters; intra-basin exports; intra-basin imports; regenerations from irrigation, domestic and industrial uses;

hydropower; and water needs for environmental purposes; excluding the constraints related to the crops. For this objective function, irrigation was considered as lumped at each major project (reservoir), i.e., in terms of the contribution of surface water in the volume of annual irrigation water required to be diverted from each reservoir, as the decision variable in the model. The next two objective functions were to maximize the annual irrigation water use, and to maximize the irrigated crop areas, respectively; with the crop areas as the decision variables in the model for both the objective functions. In the remaining two objective functions the objective was to maximize the total annual net benefits from crops, to maximize the agricultural food production in the basin, respectively. These last four objective functions were subjected to the constraints related to crops only, i.e. 5.3.6, 5.3.7, 5.3.8, and 5.3.9.

The last objective function was also subjected to the constraints of minimum food needs in the basin, i.e., 5.3.10.1, 5.3.10.2, 5.3.10.3, and 5.3.10.4.

The results of LP model for maximization of water utilization for the Cauvery river basin as a whole are given in Tables 7.1(a) to 7.1(d), Tables 7.2(a) to 7.2(d), Tables 7.3(a) to 7.3(d), and Tables 7.4(a) to 7.4(d), for 75%, 50%, 90%, and 100% water year dependable flows, respectively.

# 8.2 ANALYSIS OF LP MODEL RESULTS FOR LUMPED IRRIGATION AND WATER SUPPLY FROM MAJOR PROJECTS

#### 8.2.1 General

The LP model was run for maximization of water utilization for the Cauvery basin as a whole considering the objective function given by equation 5.2.1-I. The results obtained from the model computations are first analyzed thoroughly, keeping

in view the objectives of the problem. An adequate analysis helps in the proper decision making process, before the decisions are actually implemented in practice.

The detailed analysis of the LP model results is done (i) at the individual major project/site level, (ii) at all the sixteen sub-basins level and (iii) for the Cauvery river basin as a whole; for the 75% water year dependable flow. But, the analysis for the flows of other dependabilities is also briefly discussed. Similarly, the 5800 MCM export of water from Mettur reservoir to the sub-basins below Mettur is of main concern, and thus, the detailed analysis gives more emphasis to this aspect.

In the text below, the 'upstream' water demands at the upstream of a major project are many times referred to as 'at the medium and minor projects'; similarly, the 'downstream' water demands at the downstream of the major project are meant for 'at the major project'. This is in reference to the "upstream" and the "downstream" of a major project, i.e., a major reservoir.

# 8.2.2 Analysis at the Individual Major Project/Site Level

The analysis is done at the individual; major project or site level and, at sub-basin level; for the 75% water year dependable flow, with various export quantities from the Mettur reservoir to the sub-basins below Mettur.

In general, it is observed that for the 50%, 75%, 90% and 100% water year dependable flows, the upstream and downstream annual demands for water supply, i.e., at all the medium and minor projects, and major projects, respectively, are met satisfactorily but the upstream annual demands for irrigation at the medium and minor projects, and the downstream annual demands for irrigation at the major projects, even in the 50% water year dependable flow are not met satisfactorily at some of the projects.

The projectwise graphs of the percentage deficits in meeting various annual water demands in respect to the annual water supply and irrigation at the major, medium and minor projects above Mettur, with the annual water export from Mettur reservoir to the sub-basins below Mettur, for different water year dependable flows is presented in Figures 8.3.1 to 8.3.6.

# 8.2.2.1 Major Projects in Upper Cauvery sub-basin Above Mettur

The results show that at the major projects 1, 2, 3, 4 and 5, i.e., at the reservoirs Yagachi, Hemavathi, Harangi, Cauvery and Krishnarajsagar (KRS), the upstream annual demands for irrigation and water supply at their medium and minor projects are met satisfactorily and the downstream annual water supply demands at these major projects are also met satisfactorily, but the downstream annual irrigation demands at these major projects, except at KRS, are not met satisfactorily. The annual deficits in meeting the downstream annual irrigation demands at the major projects Yagachi, Hemavathi, Harangi, and Cauvery are 49%, 88%, 8%, and 80%, respectively.

# 8.2.2.2 Major Projects in Kabini sub-basin above Mettur

In the case of major projects 6, 7, 8, 9, 10, 11 and 12, i.e., at the reservoirs Banasursagar, Mananthvady, Kabini, Taraka, Sagardoddakere, Upper Nugu and Nugu, the downstream annual water supply demands at these major projects and the annual upstream water supply demands at their medium and minor projects are met satisfactorily, and the upstream annual irrigation demands at their medium and minor projects are also met satisfactorily, but the downstream annual irrigation demands at these major projects, except Kabini and Sagardoddakere, are not met satisfactorily.

The annual deficits in meeting the downstream annual irrigation demands at the major projects Banasursagar, Mananthvady, Taraka, Upper Nugu and Nugu are 86% 14%, 44%, 83% and 18%, respectively.

#### 8.2.2.3 Major Project in Chinnar sub-basin above Mettur

In the case of Mettur, i.e., major project 13, all the upstream annual water demands at the major project and all the upstream annual water demands at the medium and minor projects are met satisfactorily.

# 8.2.2.3 Major Projects in Bhavani, and Amaravathi sub-basins below Mettur

In the case of Bhavani and Amaravathi reservoirs, i.e., major project, 14 and 15, the upstream annual water supply demands at the medium and minor projects, and the downstream annual water supply demands at the major projects are met satisfactorily and the upstream annual irrigation demands at the medium and minor projects are also met satisfactorily, but the downstream annual irrigation demands at the major projects are not met satisfactorily. The annual deficits in meeting the downstream annual irrigation demands at Bhavani and Amaravathi are 15% and 21%, respectively.

# 8.2.3 Analysis at the Sub-Basin Level

For each water year dependable flow, the graphical presentation of the trade offs between the annual total of all the water demands met at various projects and remaining areas in a sub-basin, with the annual water exports from Mettur reservoir to the sub-basins below Mettur, for two cases, i.e., for the projects above and for the projects below Mettur are presented in Figures 8.1.1 to 8.1.5.

The percentage deficits in meeting the total of annual water demand of a given purpose in a sub-basin, i.e., the deviations from the annual total of target demands of the given purpose, for the various water exports from Mettur reservoir to the sub-basins below Mettur, for different water year dependable flows are presented in Figures 8.2.1 to 8.2.9.

The variation in annual irrigation and / or water supply from major, medium and minor projects vs. various percent water year dependable flows in various subbasins are given in Figures 8.4.1 to 8.4.9.

The demands for upstream water supply at the medium and minor projects are completely met during all the water year dependable flows.

# 8.2.3.1 Upper Cauvery sub-basin

In the case of Upper Cauvery sub-basin, the LP model results show that when water is exported from Mettur reservoir, to the sub-basins below Mettur (export equal to 5800 MCM) and to the out side the Cauvery basin; for all the water year dependable flows, the upstream annual water demands for water supply and for irrigation at the medium and minor projects are met satisfactorily, and the downstream annual demands for water supply at the major projects are also met satisfactorily. But the downstream annual demands for irrigation at the major projects are not met satisfactorily. The annual total of the deficits in the downstream annual irrigation at various major projects in the sub-basin, which are short of water, is found to be 26%, 23%, 54%, and 58% for the 75%, 50%, 90%, and 100% water year dependable flows, respectively, for the export of water from Mettur reservoir to the sub-basins below Mettur is as per the CWDTIA. The annual water utilization factor computed for this sub-basin is 0.41 for the 75% water year dependable flow, and for other flow conditions the values are estimated and given in Table 8.1.

The trade-offs between the annual total of all the water demands met at various projects and remaining areas in the sub-basin, with the annual water exports from Mettur reservoir to the sub-basins below Mettur, for various water year dependable flows, for the upstream annual demands at the medium and minor projects, and for the downstream annual demands at the major projects are given in Figures 8.1.1 to 8.1.5, respectively.

The percentage deficits in meeting the total annual water demands of a given purpose in Upper Cauvery sub-basin, i.e., the deviations from the annual total of target demands of the given purpose, at the medium and minor projects and at the major projects, for the various water exports from Mettur reservoir to the sub-basins below Mettur, for different water year dependable flows are presented in Figures 8.2.1(a) and 8.2.1(b) respectively.

The variation in annual irrigation from medium and minor projects vs. various percent water year dependable flows in the sub-basin is given in Figure 8.4.1(a). The variation in annual irrigation from major projects vs. various percent water year dependable flows in the sub-basin is given in Figure 8.4.1(b).

#### 8.2.3.2 Kabini sub-basin

In the case of Kabini sub-basin, the LP model results show that when water is exported from Mettur reservoir, to the sub-basins below Mettur (export equal to 5800 MCM) and to the out side the Cauvery basin; for all the water year dependable flows, the upstream annual water demands for water supply and for irrigation at the medium and minor projects are met satisfactorily accept for 100% water year dependable flow, the upstream annual water demands for irrigation at the medium and

minor projects, the annual total of deficit 57% is found out. The downstream annual demands for water supply at the major projects are also met satisfactorily. The downstream annual demands for irrigation at the major projects are met satisfactorily for 50% and 75% water year dependable flows. But the downstream annual demands for irrigation at the major projects for 90% and 100% water year dependable flows are not met satisfactorily. The annual total of the deficits in the downstream annual irrigation at various major projects in the sub-basin, which are short of water, is found to be 44%, and 66% for the 90% and 100% water year dependable flows, respectively, for the export of water from Mettur reservoir to the sub-basins below Mettur is as per the CWDTIA. The annual water utilization factor computed for this sub-basin is 0.73 for the 75% water year dependable flow, and for other flow conditions the values are estimated and given in Table 8.1.

The trade-offs between the annual total of all the water demands met at various projects and remaining areas in the sub-basin, with the annual water exports from Mettur reservoir to the sub-basins below Mettur, for various water year dependable flows, for the upstream annual demands at the medium and minor projects, and for the downstream annual demands at the major projects are given in Figures 8.1.1 to 8.1.5, respectively.

The percentage deficits in meeting the total annual water demands of a given purpose in Kabini sub-basin, i.e., the deviations from the annual total of target demands of the given purpose, at the medium and minor projects and at the major projects, for the various water exports from Mettur reservoir to the sub-basins below Mettur, for different water year dependable flows are presented in Figures 8.2.2(a) and 8.2s.2(b), respectively.

The variation in annual irrigation from medium and minor projects vs. various percent water year dependable flows in the sub-basin is given in Figure 8.4.2(a). The variation in annual irrigation from major projects vs. various water year dependable flows in the sub-basin is given in Figure 8.4.2(b).

#### 8.2.3.3 Shimsha sub-basin

In the case of Shimsha sub-basin, the LP model results show that when water is exported from Mettur reservoir, to the sub-basins below Mettur (export equal to 5800 MCM) and to the out side the Cauvery basin; for all the water year dependable flows, the upstream annual water demands for water supply and for irrigation at the medium and minor projects are not met satisfactorily. The annual total of the deficits in the upstream annual water demands for water supply and for irrigation at the medium and minor projects, which are short of water, is found to be (for water supply 51%, 51%, 51%, and 51%) and (for irrigation 68%, 68%, 84%, and 84%) for the 75%, 50%, 90%, and 100% water year dependable flows, respectively, for the export of water from Mettur reservoir to the sub-basins below Mettur is as per the CWDTIA. The annual water utilization factor computed for this sub-basin is 0.35 for the 75% water year dependable flow, and for other flow conditions the values are estimated and given in Table 8.1.

The trade-offs between the annual total of all the water demands met at various projects and remaining areas in the sub-basin, with the annual water exports from Mettur reservoir to the sub-basins below Mettur, for various water year dependable flows, for the upstream annual demands at the medium and minor projects, and for the downstream annual demands at the major projects are given in Figures 8.1.1 to 8.1.5, respectively.

#### 8.2.3.4 Arkavathi sub-basin

In the case of Arkavathi sub-basin, the LP model results show that when water is exported from Mettur reservoir, to the sub-basins below Mettur (export equal to 5800 MCM) and to the out side the Cauvery basin; for all the water year dependable flows, the upstream annual water demands for water supply at the medium and minor projects are met satisfactorily, but the upstream annual demands for irrigation at the medium and minor projects are not met satisfactorily. There is no any major project in this sub-basin. The annual total of the deficits in the upstream annual irrigation at various medium and minor projects in the sub-basin, which are short of water, is found to be 89%, 89%, 91%, and 92% for the 75%, 50%, 90%, and 100% water year dependable flows, respectively, for the export of water from Mettur reservoir to the sub-basins below Mettur is as per the CWDTIA. The annual water utilization factor computed for this sub-basin is 0.30 for the 75% water year dependable flow, and for other flow conditions the values are estimated and given in Table 8.1.

The trade-offs between the annual total of all the water demands met at various projects and remaining areas in the sub-basin, with the annual water exports from Mettur reservoir to the sub-basins below Mettur, for various water year dependable flows, for the upstream annual demands at the medium and minor projects, and for the downstream annual demands at the major projects are given in Figures 8.1.1 to 8.1.5, respectively.

The percentage deficits in meeting the total annual water demands of a given purpose in Arkavathi sub-basin, i.e., the deviations from the annual total of target demands of the given purpose, at the major projects and at the medium and minor, and major projects, for the various water exports from Mettur reservoir to the sub-

basins below Mettur, for different water year dependable flows are presented in Figures 8.2.3(a) and 8.2.3(b), respectively.

The variation in annual water supply from major projects vs. various percent water year dependable flows in the sub-basin is given in Figure 8.4.3(a). The variation in annual total water supply from major, medium and minor projects vs. various percent water year dependable flows in the sub-basin is given in Figure 8.4.3(b).

#### 8.2.3.5 Middle Cauvery sub-basin

In the case of Middle Cauvery sub-basin, the LP model results show that when water is exported from Mettur reservoir, to the sub-basins below Mettur (export equal to 5800 MCM) and to the out side the Cauvery basin; for all the water year dependable flows, the upstream annual water demands for water supply at the medium and minor projects are met satisfactorily. The upstream annual demands for irrigation at the medium and minor projects are met satisfactorily for 50% water year dependable flows. But the upstream annual demands for irrigation at the medium and minor projects are not met satisfactorily for 75%, 90% and 100% water year dependable flows. The annual total of the deficits in the upstream annual irrigation at various major projects in the sub-basin, which are short of water, is found to be 6%, 6%, and 6% for the 75%, 90%, and 100% water year dependable flows, respectively, for the export of water from Mettur reservoir to the sub-basins below Mettur is as per the CWDTIA. The annual water utilization factor computed for this sub-basin is 0.77 for the 75% water year dependable flow, and for other flow conditions the values are estimated and given in Table 8.1.

The trade-offs between the annual total of all the water demands met at various projects and remaining areas in the sub-basin, with the annual water exports

from Mettur reservoir to the sub-basins below Mettur, for various water year dependable flows, for the upstream annual demands at the medium and minor projects, and for the downstream annual demands at the major projects are given in Figures 8.1.1 to 8.1.5, respectively.

The percentage deficits in meeting the total annual water demands of a given purpose in Middle Cauvery sub-basin, i.e., the deviations from the annual total of target demands of the given purpose, at the medium and minor projects and at the major projects, for the various water exports from Mettur reservoir to the sub-basins below Mettur, for different water year dependable flows are presented in Figures 8.2.4(a) and 8.2.4(b), respectively.

The variation in annual total irrigation from major, medium and minor projects vs. various percent water year dependable flows in the sub-basin is given in Figure 8.4.4.

#### 8.2.3.6 Suvarnavathi sub-basin

In the case of Suvarnavathi sub-basin, the LP model results show that when water is exported from Mettur reservoir, to the sub-basins below Mettur (export equal to 5800 MCM) and to the out side the Cauvery basin, for all the water year dependable flows, the upstream annual water demands for water supply and for irrigation at the medium and minor projects are met satisfactorily. But the upstream annual demands for irrigation at the medium and minor projects are not met satisfactorily. The annual total of the deficits in the upstream annual irrigation at various medium and minor projects in the sub-basin, which are short of water, is found to be 90%, 88%, 94%, and 94% for the 75%, 50%, 90%, and 100% water year

dependable flows, respectively, for the export of water from Mettur reservoir to the sub-basins below Mettur is as per the CWDTIA. The annual water utilization factor computed for this sub-basin is 0.20 for the 75% water year dependable flow, and for other flow conditions the values are estimated and given in Table 8.1.

The trade-offs between the annual total of all the water demands met at various projects and remaining areas in the sub-basin, with the annual water exports from Mettur reservoir to the sub-basins below Mettur, for various water year dependable flows, for the upstream annual demands at the medium and minor projects, and for the downstream annual demands at the major projects are given in Figures 8.1.1 to 8.1.5, respectively.

The percentage deficits in meeting the total annual water demands of a given purpose in Suvarnavathi sub-basin, i.e., the deviations from the annual total of target demands of the given purpose, at the medium and minor projects, for the various water exports from Mettur reservoir to the sub-basins below Mettur, for different water year dependable flows are presented in Figures 8.2.5(a) and 8.2.5(b), respectively.

#### 8.2.3.7 Palar sub-basin

In the case of Palar sub-basin, the LP model results show that when water is exported from Mettur reservoir, to the sub-basins below Mettur (export equal to 5800 MCM) and to the out side the Cauvery basin; for all the water year dependable flows, the upstream annual water demands for water supply at the medium and minor projects are met satisfactorily. But the upstream annual demands for irrigation at the medium and minor projects are not met satisfactorily. The annual total of the deficits

in the upstream annual irrigation at various medium and minor projects in the sub-basin, which are short of water, is found to be 54%, 10%, 57%, and 62% for the 75%, 50%, 90%, and 100% water year dependable flows, respectively, for the export of water from Mettur reservoir to the sub-basins below Mettur is as per the CWDTIA. The annual water utilization factor computed for this sub-basin is 0.60 for the 75% water year dependable flow, and for other flow conditions the values are estimated and given in Table 8.1.

The trade-offs between the annual total of all the water demands met at various projects and remaining areas in the sub-basin, with the annual water exports from Mettur reservoir to the sub-basins below Mettur, for various water year dependable flows, for the upstream annual demands at the medium and minor projects, and for the downstream annual demands at the major projects are given in Figures 8.1.1 to 8.1.5, respectively.

#### 8.2.3.8 Chinnar sub-basin

In the case of Chinnar sub-basin, the LP model results show that when water is exported from Mettur reservoir, to the sub-basins below Mettur (export equal to 5800 MCM) and to the out side the Cauvery basin; for all the water year dependable flows, the upstream annual water demands for water supply and for irrigation at the medium and minor projects are met satisfactorily. The annual water utilization factor computed for this sub-basin is 1.00 for the 75% water year dependable flow, and for other flow conditions the values are estimated and given in Table 8.1.

The trade-offs between the annual total of all the water demands met at various projects and remaining areas in the sub-basin, with the annual water exports from Mettur reservoir to the sub-basins below Mettur, for various water year

dependable flows, for the upstream annual demands at the medium and minor projects, and for the downstream annual demands at the major projects are given in Figures 8.1.1 to 8.1.5, respectively.

The variation in annual total irrigation from major, medium and minor projects vs. various percent water year dependable flows in the sub-basin is given in Figure 8.4.5.

# 8.2.3.9 Bhavani sub-basin

In the case of Bhavani sub-basin, the LP model results show that when water is exported from Mettur reservoir, to the sub-basins below Mettur (export equal to 5800 MCM) and to the out side the Cauvery basin; for all the water year dependable flows, the upstream annual water demands for water supply and for irrigation at the medium and minor projects are met satisfactorily accept for 100% water year dependable flow, where the deficit is of 12% is found out for irrigation; and the downstream annual water demands for water supply and irrigation at the major projects are also met satisfactorily, for the export of water from Mettur reservoir to the sub-basins below Mettur is as per the CWDTIA. The annual water utilization factor computed for this sub-basin is 0.52 for the 75% water year dependable flow, and for other flow conditions the values are estimated and given in Table 8.1.

The trade-offs between the annual total of all the water demands met at various projects and remaining areas in the sub-basin, with the annual water exports from Mettur reservoir to the sub-basins below Mettur, for various water year dependable flows, for the upstream annual demands at the medium and minor projects, and for the downstream annual demands at the major projects are given in Figures 8.1.1 to 8.1.5, respectively.

#### 8.2.3.10 Noyil sub-basin

In the case of Noyil sub-basin, the LP model results show that when water is exported from Mettur reservoir, to the sub-basins below Mettur (export equal to 5800 MCM) and to the out side the Cauvery basin; for all the water year dependable flows, the upstream annual water demands for water supply and for irrigation at the medium and minor projects are not met satisfactorily. The annual total of the deficits in the upstream annual water supply and irrigation at various medium and minor projects in the sub-basin, which are short of water, is found to be (for water supply 65%, 65%, 65%, and 65%) and (for irrigation 97%, 97%, 97%, and 97%) for the 75%, 50%, 90%, and 100% water year dependable flows, respectively, for the export of water from Mettur reservoir to the sub-basins below Mettur is as per the CWDTIA. The annual water utilization factor computed for this sub-basin is 0.19 for the 75% water year dependable flow, and for other flow conditions the values are estimated and given in Table 8.1.

The trade-offs between the annual total of all the water demands met at various projects and remaining areas in the sub-basin, with the annual water exports from Mettur reservoir to the sub-basins below Mettur, for various water year dependable flows, for the upstream annual demands at the medium and minor projects, and for the downstream annual demands at the major projects are given in Figures 8.1.1 to 8.1.5, respectively.

The variation in annual total water supply from major project vs. various percent water year dependable flows in the sub-basin is given in Figure 8.4.6(a).

#### 8.2.3.11 Amaravathi sub-basin

In the case of Amaravathi sub-basin, the LP model results show that when water is exported from Mettur reservoir, to the sub-basins below Mettur (export equal

to 5800 MCM) and to the out side the Cauvery basin; for all the water year dependable flows, the upstream and downstream annual water demands for water supply at the medium and minor, and major projects are met satisfactorily. But the upstream and downstream annual demands for irrigation at the medium and minor projects and major projects, respectively, are not met satisfactorily. The annual total of the deficits in the upstream and downstream annual irrigation at various medium and minor, and major projects, respectively, in the sub-basin, which are short of water, is found to be (for medium and minor project 69%, 68%, 77%, and 78%) and (for major projects 3%, 24%, 24% and 84%) for the 75%, 50%, 90%, and 100% water year dependable flows, respectively, for the export of water from Mettur reservoir to the sub-basins below Mettur is as per the CWDTIA. The annual water utilization factor computed for this sub-basin is 0.62 for the 75% water year dependable flow, and for other flow conditions the values are estimated and given in Table 8.1.

The trade-offs between the annual total of all the water demands met at various projects and remaining areas in the sub-basin, with the annual water exports from Mettur reservoir to the sub-basins below Mettur, for various water year dependable flows, for the upstream annual demands at the medium and minor projects, and for the downstream annual demands at the major projects are given in Figures 8.1.1 to 8.1.5, respectively.

The percentage deficits in meeting the total annual water demands of a given purpose in Amaravathi sub-basin, i.e., the deviations from the annual total of target demands of the given purpose, at the medium and minor projects and at the major projects, for the various water exports from Mettur reservoir to the sub-basins below Mettur, for different water year dependable flows are presented in Figures 8.2.6(a), 8.2.6(b), and 8.2.6(c), respectively.

The variation in annual irrigation from medium and minor projects vs. various water year dependable flows in the sub-basin is given in Figure 8.4.7(a). The variation in annual irrigation from major projects vs. various water year dependable flows in the sub-basin is given in Figure 8.4.7(b). The variation in annual irrigation from major, medium and minor projects vs. various water year dependable flows in the sub-basin is given in Figure 8.4.7(c).

#### 8.2.3.12 Tirumanimuttar sub-basin

In the case of Tirumanimuttar sub-basin, the LP model results show that when water is exported from Mettur reservoir, to the sub-basins below Mettur (export equal to 5800 MCM) and to the out side the Cauvery basin; for all the water year dependable flows, the upstream annual water demands for water supply at the medium and minor projects are met satisfactorily. But the upstream annual demands for irrigation at the medium and minor projects are not met satisfactorily. The annual total of the deficits in the upstream annual irrigation at various medium and minor projects in the sub-basin, which are short of water, is found to be 91%, 89%, 93%, and 948% for the 75%, 50%, 90%, and 100% water year dependable flows, respectively, for the export of water from Mettur reservoir to the sub-basins below Mettur is as per the CWDTIA. The annual water utilization factor computed for this sub-basin is 0.36 for the 75% water year dependable flow, and for other flow conditions the values are estimated and given in Table 8.1.

The trade-offs between the annual total of all the water demands met at various projects and remaining areas in the sub-basin, with the annual water exports from Mettur reservoir to the sub-basins below Mettur, for various water year dependable flows, for the upstream annual demands at the medium and minor

projects, and for the downstream annual demands at the major projects are given in Figures 8.1.1 to 8.1.5, respectively.

The percentage deficits in meeting the total annual water demands of a given purpose in Tirumanimuttar sub-basin, i.e., the deviations from the annual total of target demands of the given purpose, at the medium and minor projects and at the major projects, for the various water exports from Mettur reservoir to the sub-basins below Mettur, for different water year dependable flows are presented in Figures 8.2.7(a), 8.2.7(b) and 8.2.7(c), respectively.

The variation in annual total irrigation from major, medium and minor projects vs. various percent water year dependable flows in the sub-basin is given in Figures 8.4.8(a). The variation in annual total water supply from major project vs. various percent water year dependable flows in the sub-basin is given in Figure 8.4.8(b). The variation in annual total water supply from major, medium and minor projects vs. various percent water year dependable flows in the sub-basin is given in Figure 8.4.8(c).

#### 8.2.3.13 Ponnanai Ar sub-basin

In the case of Ponnanai Ar sub-basin, the LP model results show that when water is exported from Mettur reservoir, to the sub-basins below Mettur (export equal to 5800 MCM) and to the out side the Cauvery basin; for all the water year dependable flows, the upstream annual water demands for water supply at the medium and minor projects are met satisfactorily. But the upstream annual demands for irrigation at the medium and minor projects are not met satisfactorily. The annual total of the deficits in the upstream annual irrigation at various medium and minor projects in the sub-basin, which are short of water, is found to be 55%, 54%, 56%,

and 57% for the 75%, 50%, 90%, and 100% water year dependable flows, respectively, for the export of water from Mettur reservoir to the sub-basins below Mettur is as per the CWDTIA. The annual water utilization factor computed for this sub-basin is 0.52 for the 75% water year dependable flow, and for other flow conditions the values are estimated and given in Table 8.1.

The trade-offs between the annual total of all the water demands met at various projects and remaining areas in the sub-basin, with the annual water exports from Mettur reservoir to the sub-basins below Mettur, for various water year dependable flows, for the upstream annual demands at the medium and minor projects, and for the downstream annual demands at the major projects are given in Figures 8.1.1 to 8.1.5, respectively.

The percentage deficits in meeting the total annual water demands of a given purpose in Ponnanai Ar sub-basin, i.e., the deviations from the annual total of target demands of the given purpose, at the medium and minor projects and major projects, for the various water exports from Mettur reservoir to the sub-basins below Mettur, for different water year dependable flows are presented in Figure 8.2.8.

The variation in annual irrigation from major, medium and minor projects vs... various percent water year dependable flows in the sub-basin is given in Figure 8.4.9.

# 8.2.3.14 Upper Coleroon sub-basin

In the case of Upper Coleroon sub-basin, the LP model results show that when water is exported from Mettur reservoir, to the sub-basins below Mettur (export equal to 5800 MCM) and to the out side the Cauvery basin; for all the water year dependable flows, the upstream annual water demands for water supply at the medium and minor projects are met satisfactorily. But the upstream annual demands

for irrigation at the medium and minor projects are not met satisfactorily. The annual total of the deficits in the upstream annual irrigation at various medium and minor projects in the sub-basin, which are short of water, is found to be 26%, 23%, 27%, and 28% for the 75%, 50%, 90%, and 100% water year dependable flows, respectively, for the export of water from Mettur reservoir to the sub-basins below Mettur is as per the CWDTIA. The annual water utilization factor computed for this sub-basin is 0.63 for the 75% water year dependable flow, and for other flow conditions the values are estimated and given in Table 8.1.

The trade-offs between the annual total of all the water demands met at various projects and remaining areas in the sub-basin, with the annual water exports from Mettur reservoir to the sub-basins below Mettur, for various water year dependable flows, for the upstream annual demands at the medium and minor projects, and for the downstream annual demands at the major projects are given in Figures 8.1.1 to 8.1.5, respectively.

#### 8.2.3.15 Lower Coleroon sub-basin

In the case of Lower Coleroon sub-basin, the LP model results show that when water is exported from Mettur reservoir, to the sub-basins below Mettur (export equal to 5800 MCM) and to the out side the Cauvery basin; for all the water year dependable flows, the upstream annual water demands for water supply at the medium and minor projects are met satisfactorily. But the upstream annual demands for irrigation at the medium and minor projects are not met satisfactorily. The annual total of the deficits in the upstream annual irrigation at various major projects in the sub-basin, which are short of water, is found to be 46%, 43%, 48%, and 49% for the 75%, 50%, 90%, and 100% water year dependable flows, respectively, for the export

of water from Mettur reservoir to the sub-basins below Mettur is as per the CWDTIA. The annual water utilization factor computed for this sub-basin is 0.50 for the 75% water year dependable flow, and for other flow conditions the values are estimated and given in Table 8.1.

The trade-offs between the annual total of all the water demands met at various projects and remaining areas in the sub-basin, with the annual water exports from Mettur reservoir to the sub-basins below Mettur, for various water year dependable flows, for the upstream annual demands at the medium and minor projects, and for the downstream annual demands at the major projects are given in Figures 8.1.1 to 8.1.5, respectively.

#### 8.2.3.16 Cauvery Delta sub-basin

In the case of Cauvery Delta sub-basin, the LP model results show that when water is exported from Mettur reservoir, to the sub-basins below Mettur (export equal to 5800 MCM) and to the out side the Cauvery basin; for all the water year dependable flows, the upstream annual water demands for water supply at the medium and minor projects are met satisfactorily. But the upstream annual demands for irrigation at the medium and minor projects are not met satisfactorily. The annual total of the deficits in the downstream annual irrigation at various major projects in the sub-basin, which are short of water, is found to be 63%, 62%, 64%, and 65% for the 75%, 50%, 90%, and 100% water year dependable flows, respectively, for the export of water from Mettur reservoir to the sub-basins below Mettur is as per the CWDTIA. The annual water utilization factor computed for this sub-basin is 0.40 for the 75% water year dependable flow, and for other flow conditions the values are estimated and given in Table 8.1.

The trade-offs between the annual total of all the water demands met at various projects and remaining areas in the sub-basin, with the annual water exports from Mettur reservoir to the sub-basins below Mettur, for various water year dependable flows, for the upstream annual demands at the medium and minor projects, and for the downstream annual demands at the major projects are given in Figures 8.1.1 to 8.1.5, respectively.

#### 8.3 ANALYSIS OF LP MODEL RESULTS WITH CROP CONSIDERATIONS

#### 8.3.1 General

The LP model was run for the objective functions given by equations 5.2.1-II, 5.2.2, 5.2.3 and 5.2.4, with crops being considered as the decision variables in the model, and the results were obtained for all the objectives for analysis, only for the 75% annual dependable flow. The model runs were made at the individual project/site level, i.e., for all the 15 major projects in the Cauvery river system. The surface water contribution as diversions for irrigation from a reservoir, were made available from the LP model results in Section 8.2. Similarly, the ground water contributions towards irrigation were also obtained from the results in Section 8.2. The model was run for monthly time periods on an annual basis. The results are given in Table 7.2.1 to Table 7.2.15.

### 8.3.2 Analysis at the Individual Project/Site Level

# 8.3.2.1 Major Projects in Upper Cauvery sub-basin above Mettur

The results show that at the major projects 1,2,3,4 and 5, i.e., at the reservoirs Yagachi, Hemavathi, Harangi, Cauvery and Krishnarajsagar (KRS), the annual water diversions made available for irrigation from each reservoir and the annual ground

water available, is sufficient to meet the irrigation water needs for the crop areas proposed in the project report, in order to maximize the objective functions for (i) maximization of area to be irrigated, (ii) maximization of annual irrigation water utilization and (iii) maximization of the total annual returns from the crops in the respective sub-basins. But in order to maximize the objective function for annual food production from various crops, to meet the minimum food requirements of the agricultural population in the command areas of the respective major projects, these available annual water diversions and the ground water resource is not sufficient. From the model results in Table 7.2.1, it is seen that, this deficiency in water availability in meeting the irrigation water requirements of the crops at Yagachi, resulted in crop areas for the pulses and oilseed are 13% and 42%, of crop areas mentioned in the project report and 53% for oilseeds of the minimum crop areas needed for the minimum annual food production, respectively.

In case of Hemavathi (Table 7.2.2), the deficiency in water availability in meeting the irrigation water requirements of the crops for the pulses, oilseeds and vegetables are 43%, 100% and 100%, respectively. In case of the Harangi, Cauvery and KRS projects, the irrigation water demands for the cereal crops are met satisfactorily, but the irrigation water demands for pulses and oil seeds are not met at all.

# 8.3.2.2 Major Projects in Kabini sub-basin above Mettur

In case of the sites 6, 7, 8, 9, 10, 11 and 12, i.e., at the reservoirs Banasursagar, Mananthvady, Kabini, Taraka, Sagardoddakere, Upper Nugu and Nugu, the annual demands for irrigation projects for the proposed crop areas for the objective functions for (i) maximization of area to be irrigated, (ii) maximization of annual water

utilization and (iii) maximization of net benefits from the crops proposed in the respective sub-basins are met satisfactorily. But the annual water demands for the crop area for the objective function of maximization of food production to meet the minimum food requirements of the agricultural population in the command areas of the respective major projects are not met satisfactorily. In the objective function of maximization of food production to meet the minimum food requirements of the agricultural population in the command areas of the respective major projects in case of the sites 7, 9 and 11, i.e., at the reservoirs Mananthvady, Taraka and Nugu the irrigation annual water demands are not met satisfactorily. In case of Mananthvady project the annual irrigation requirements satisfied for the crops are 0%, 0%, 26%, 2%, 24%, and 2% for Kharif Paddy, Kharif Jowar, Ragi, pulses, fruits and vegetables, and groundnut, respectively. In case of Upper Nugu the annual irrigation demands satisfied for Kharif Paddy, Rabi Paddy and groundnut are 31%, 10% and 16% respectively. The annual irrigation demands incase of pulses and fruit and vegetables are 300% and 160% respectively.

# 8.3.2.3 Major Projects in Chinnar sub-basin above Mettur

In case of the Mettur reservoir, i.e., major project 13, the annual demands for irrigation projects for the proposed crop areas for the objective functions for (i) maximization of area to be irrigated, (ii) maximization of annual water utilization and (iii) maximization of net benefits from the crops proposed in the respective subbasins are met satisfactorily. The annual irrigation demands for the cereal crops are met satisfactorily. In case of Mettur the irrigation demand for minimum food requirement case the pulses of 150% area can be irrigated, for oil crops the demand is satisfied 33%.

#### 8.3.2.4 Major Projects in Bhavani, and Amaravathi sub-basins below Mettur

In case of the Bhavani and Amaravathi reservoirs, i.e., major projects 14 and 15, the annual demands for irrigation projects for the proposed crop areas for the objective functions for (i) maximization of area to be irrigated, (ii) maximization of annual water utilization and (iii) maximization of net benefits from the crops proposed in the respective sub-basins are met satisfactorily. The annual irrigation demands for the cereal crops are met satisfactorily. In case of lower Bhavani the Kharif Paddy the irrigation of 60% is possible.

Table 8.1: Computed Annual Water Utilization Factors from LP Model Results
Under Different Scenario for 75% Water Year Dependable Flow

| Sl.No.      | Name of Sub-Basins | Exports from<br>Mettur Reservoir | utilization factor-with |                      |              |      |              |                           |

Note: (1) sw = Surface water; sw + imp = Surface water + imports.

sw + imp + swr = Surface water + imports + regenerations from surface water use;

g.w. = Ground water

gw+gwr = Ground water + regenerations from ground water use

sw+imp+swr+gw+gwr = Surface water + imports + regenerations from surface water use + ground water + regenerations from ground water use

- (2) The utilization factors calculated from LP model, where, if the utilization factor is less than one, the surplus water is available; however, when the utilization factor is equal to one, it means the demands are completely met with the following interpretations:
  - (i) the available water is less than the demands, and (ii) the available water is more than the demands and a part of available water is being diverted optimally to downstream sub-basins. This shows the impact of storages and locations on water utilization. This is because, the entire river system is considered as one, unlike in water balance studies where each sub-basin was considered independently.

The annual water utilization factor is defined as the ratio of the amount of water utilized and total quantity of water available from surface water and ground water.

#### SUMMARY OF FINDINGS AND CONCLUSIONS

#### 9.1 INTRODUCTION

The present study was carried out with an overall objective of comprehensive analysis for optimal water utilization, with intra-basin and inter-basin water transfers considerations for an interstate Cauvery river system, in respect to the interim award of Cauvery Water Dispute Tribunal (CWDTIA) to release at the Mettur reservoir 5800 MCM (205 Million Cubic Feet) of water, which is the contribution from the upper riparian Karnataka state to the lower riparian Tamilnadu state. The river system was presented in Chapter 3. It was very important to assess the surface and ground waters available and its utilization, in the basin on monthly basis. Therefore, this study may be of great importance from actual field application point of view. The details of the studies are sequentially presented in the previous chapters. The presentation in this chapter begins with an overall view of the studies carried out. The subsequent section comprises of the summary of findings of the different aspects of the work accomplished. Finally, conclusions drawn from the overall study are presented in this chapter. Some suggestions are made at the end of this chapter to outline the scope for further related studies.

#### 9.2 AN OVERALL VIEW OF THE PROBLEM

The Cauvery is an inter state river in South India originating in the state of Karnataka and flowing through the states of Karnataka, Kerala, Tamilnadu, and Pondicherry having a catchment area of 81,155 Km<sup>2</sup>. The state wise drainage areas of

Cauvery basin are Karnataka 34,273 Km<sup>2</sup> (42.2%); Tamilnadu 43,867 Km<sup>2</sup> (54.1%); Kerala 2,866 Km<sup>2</sup> (3.5)% and Pondicherry 149 Km<sup>2</sup> (0.2)%. This basin has 16-sub-basins. It has 75% and 50% water year dependable surface water potential of 16,470 MCM and 20,253 MCM, respectively. A total of 3,866 MCM ground water potential is available for future use. The water requirement for the population of human and livestock projected to the year 2050AD for all purposes as estimated in Chapter 4 is 39516 MCM. There are 15 major projects (reservoirs), 58 medium and a large number of minor irrigation projects in the basin. The total irrigable area is 2605200 Ha.

The Supreme Court of India has recently given directives to the Government of India for interlinking of the major rivers of the Himalayan and Peninsular regions for transfer of waters from the water surplus river basins to the water deficit basins to reduce the natural imbalance of the water availability in various basins in the country. The studies on various inter-basin water transfers are carried out, usually on the basis of annual water balance of all the sub-basins lying in the respective major river basins involved, to determine the amount of water available and to identify the water surplus and water deficit basins. But in this study, the monthly water balance studies on an annual basis are carried out for various water year dependable flows. The previous studies carried out for the water balance accounting on an annual basis, do not take into account: (i) the availability and use of the ground water, (ii) the time wise variability and distribution of the water availability with respect to the yearly and within the year time periods, and (iii) the aerial variability and distribution of the water available and its use in a basin/ sub-basin, with respect to the location of the various reservoirs and water use points. In this study to overcome the above mentioned three drawbacks in the previous studies for water balance carried out by conventional method, elsewhere for

the Cauvery river basin, the monthly water balance on annual basis is carried out to overcome the first two drawbacks, and a Linear Programming (LP) optimization model to overcome all the three drawbacks.

The methodology adopted to achieve the objectives is outlined below:

### (A) Sub-basinwise Monthly Water Balance Studies

The monthly water balance studies were made to know the surplus and deficits to find out whether the monthly water requirements are met or not and whether the monthly intra-basin water transfers within the Cauvery basin are possible.

# (1) Estimation of surface water and ground water potential

The 75% water year dependable surface water yields on monthly basis for each sub-basin were calculated by distributing the annual 75% water year dependable yields in the proportion of actual average monthly inflows/yields observed at the nearest gauge and discharge (G&D) site within or outside of the sub-basin. The sub-basinwise ground water potential and the existing uses were computed on the area basis from districtwise ground water statistics, the data collected from the Water Resources of India, a publication of Central Ground Water Board, under the Ministry of water Resources, Government of India, Faridabad. The same procedure was adopted for 50%, 90% and 100% water year dependable flows.

# (2) Assessment of the water requirements/needs

# (a) Irrigation water requirements/needs

The irrigation needs were calculated by keeping the utilization of existing and ongoing major, medium and minor projects undisturbed while the net and gross crop water requirements for future major, medium and minor projects have been worked out by climatological approach. It was considered that at least 30% of the maximum culturable area for each sub-basin should be under irrigation for the year 2050 AD and

in case of sub-basins having less than 30% of irrigation area, the additional area to be brought under irrigation was computed and 50% of this was proposed to be irrigated from future medium projects and the remaining 50% from future minor projects. The ultimate irrigation needs for the future projects are calculated and are used for the water balance studies.

#### (b) Domestic water requirements/needs

The rural, urban and livestock population had been computed by projecting the 1981 census human population and 1982/83 census livestock population to 2050 AD by using suitable compound annual growth rates for human population and one percent for livestock population. The domestic water requirements were calculated considering the per capita water requirements of 70 liters, 200 liters and 50 liters per day respectively as per the NWDA norms. The urban population by 2050 AD is taken as 60.70% of the total projected population by 2050 AD. The entire water requirement for the urban population and the 50% of the rural population was proposed to be met from surface water. The entire water requirement for live stock population and 50% of the requirement for the rural population was proposed to be met from ground water resources.

# (c) Industrial water requirements/needs

For the industrial water requirements, in the absence of relevant data, it had been assumed to be of same order as that of domestic water requirements by 2050 AD.

# (d) Hydropower water requirements/needs

The total evaporation losses of all single purpose hydropower projects in the catchment area of each sub-basin are considered, as hydropower needs.

# (e) Environmental water requirements/needs

The environmental needs in each month are taken equal to 1% of the inflows of those months.

The intra-basin water transfer quantities are taken from the data collected from NWDA. The regeneration from irrigation, domestic and industrial was taken as 10%, 80%, and 80% of net utilization, respectively. The monthly and annual water balances for each month in each sub-basin were calculated and the monthly and annual surplus and deficits were worked out.

## (B) The Mathematical Modeling Approach

- (1) The optimization model for planning and management was considered suitable for this study in view of the large size of problem to be addressed. The study involved modeling for water transfers to other irrigation areas and the interest of co-basin riparian states (bases on sharing of the river water and limitations of its use under numerous location specific hydrological, techno-economic and management constraints pertaining to agreements and CWDT award. In accordance with the reported findings, regarding the modeling approaches, and the nature and scope of the present study, and huge number of variables to be handled the linear programming model was found to be promising.
- (2) To study the effects of the spatial variations with respect to project sites and reservoir storage on the water balance of the system, a project-by-project analysis, and sub-basin wise analysis were carried out.
- (3) The optimization model was run for 75%, 50%, 90%, and 100% water year dependable flows by using LINDO software package for solution. Irrigation was considered as lumped. The monthly diversions from reservoirs and ground water were obtained.
- (4) The cropping pattern was studied for each reservoir. The water availability was taken from step (3) above. The cropping patterns were analyzed keeping in mind (a) The number of paddy crops to be grown, (b) Reducing the area for water extensive crops, and (c) Opting for high revenue crops.
- (5) To see the effect of the water surplus and the water deficit years on the water utilization and on intra basin water transfers, the step (4) was repeated.

- (6) The minimum food requirement with respect to calorific value of crops was also studied.
- (7) The above studies also include the consideration of the interim award of Cauvery Water Dispute Tribunal (CWDTIA).

# 9.3 THE WORKS ACCOMPLISHED

The detailed monthly water balance studies on an annual basis for the sixteen sub-basins of Cauvery river system for various water year dependable flows, i.e., (i) 75% water year annual dependable flow representing a water year under normal conditions, (ii) 90% water year annual dependable flow representing a water deficit year, (iii) 100% (lowest flow) water year annual dependable flow representing a critical water deficit year, and (iv) 50% water year annual dependable annual flow representing a water surplus year, are carried out with considerations of ground water and the environmental water requirements. The monthly water balances, without considering the ground water availability in the sub-basin and with the ground water considerations, are carried out and presented in Chapter 4. The Linear Programming (LP) Model is developed and presented in Chapter 5, for the intra-basin water transfers among the various sub-basins. Chapter 6 deals with computation of input data for linear programming model. The LP model is applied to the Cauvery river system, for conjunctive water use development in the basin, taking care of the interim award of Cauvery Water Dispute Tribunal, and presented in Chapter 7. Crop plans are also derived for each major reservoir in the basin. Chapter 8 deals with analysis of linear programming model.

#### 9.4 SUMMARY OF FINDINGS

# 9.4.1 Water Balance Studies for 75% Water Year Dependable Flows With and Without Ground Water Considerations by Conventional Method

The monthly water balance on an annual basis, with and without ground water considerations, of the sub-basins of the Cauvery river carried out for four water year dependable flows in this thesis. The account of the water balance for 75% water year dependable flow is given in Table 9.1.

Table 9.1: Sub-basin wise Annual Surplus/Deficit in Cauvery Basin from Water Balance for 75% Water Year Dependable Flow

| Sl.No. | Name of sub-basin | Without ground water | With ground water |
|--------|-------------------|----------------------|-------------------|
| (1)    | (2)               | (3)                  | (4)               |
| 1      | Upper Cauvery     | -275.46              | 303.04            |
| 2      | Kabini            | -271.11              | 115.29            |
| 3      | Shimsha           | 150.72               | 656.72            |
| 4      | Arkavathi         | -799.19              | -695.69           |
| 5      | Middle Cauvery    | 66.89                | 272.49            |
| 6      | Suvarnavathi      | -79.64               | -15.74            |
| 7      | Palar             | -161.49              | -21.79            |
| 8      | Chinnar           | -13103.10            | -12932.21         |
| 9      | Bhavani           | -423.60              | -235 90           |
| 10     | Noyil             | -66.40               | -31.19            |
| 11     | Amaravathi        | -750.62              | -442.62           |
| 12     | Tirumanimuttar    | -225.89              | 124.24            |
| 13     | Ponnanai Ar       | -13.7109             | 193.69            |
| 14     | Upper Coleroon    | 86.64                | 339.24            |
| 15     | Lower Coleroon    | 222.16               | 342.76            |
| 16     | Cauvery Delta     | 1203.06              | 1611.16           |
| Total  |                   | -14440.70            | -10416.21         |

Note: Export from Mettur reservoir is 12712 MCM.

The water balance study of sixteen sub-basins of Cauvery river basin for the 75% water year dependable flow with ground water availability considerations, show that Table 9.1, on an annual basis, four of them, i.e., Upper Cauvery, Kabini, Tirumanimuttar and Ponnanai Ar have become water surplus from water deficit; seven of them, i.e., Arkavathi, Suvarnavathi, Palar, Chinnar, Bhavani, Noyil and Amaravathi remain still water deficit.

The sub-basin wise monthly deficits in descending order computed from water balance studies with ground water consideration for 75% water year dependable flows for the Cauvery basin are presented in Table 9.2(a) to Table 9.2(d).

From the results of water balance studies for 75% water year dependable flow without and with the considerations of the ground water, the following observations are made.

#### 9.4.1.1 Upper Cauvery sub-basin

In the Upper Cauvery sub-basin it is found that with the ground water availability considerations [refer Table 4.14.1], the maximum water surplus in the sub-basin is increased from 598.37 MCM (9.5 %) to 703.58 MCM (11.01%) in the month of July and the minimum water surplus in the sub-basin is increased from 16.50 MCM (0.26%) to 18.00 MCM (0.29%) in the month of May. The maximum water deficit has reduced from (-391.29) MCM (-6.21%) to (-277.58) MCM (-4.34%) in the month of October and the minimum water deficit of (-17.62) MCM (-0.28%) in the sub-basin is reduced to (-11.32) MCM (0.18%) with the ground water considerations in the month of November. The sub-basin has become water surplus from water deficit on an annual basis due to consideration of ground water availability. The amount of annual water deficit has changed from (-274.45) MCM (-4.36%) to 286.45 MCM (4.48%) in the sub-basin with the ground water availability.

#### 9.4.1.2 Kabini sub-basin

In the Kabini sub-basin it is found that with the ground water availability considerations [refer Table 4.14.2], the maximum water surplus in the sub-basin is increased from 132.86 MCM (2.7%) in the month of June to 192.31 MCM (3.87%) and the minimum water surplus in the sub-basin is increased from 4.46 MCM (0.10%) to 21.54 MCM (0.43%) in the month of November. The maximum water deficit has reduced from (-253.08) MCM (-5.1%) to (-202.50) MCM (-4.07%) in the month of January and the minimum water deficit of (-5.67) MCM (-0.10%) in the sub-basin is reduced to (-0.85) MCM (-0.02%) with the ground water considerations in the month of April. The sub-basin has become water surplus from water deficit on an annual basis due to consideration of ground water availability. The amount of annual water deficit has changed from (-267.77) MCM (-5.4%) to 107.62 MCM (2.16%) in the sub-basin with the ground water availability.

#### 9.4.1.3 Shimsha sub-basin

In the Shimsha sub-basin it is found that with the ground water availability considerations [refer Table 4.14.3], the maximum water surplus in the sub-basin is increased from 294.72 MCM (7.80%) to 299.95 MCM (7.75%) in the month of October and the minimum water surplus in the sub-basin is increased from 2.42 MCM (0.06%) to 8.86 MCM (0.23%) in the month of May. The maximum water deficit has reduced from (-68.87) MCM (-1.82%) to (-2.49) MCM (-0.06%) in the month of April and the minimum water deficit of (-0.25) MCM (-0.01%) in the sub-basin is reduced to (-2.49) MCM (0.06%) with the ground water considerations in the month of November. The amount of annual surplus water has increased from 150.81 MCM (3.99%) to 640.15 MCM (16.55%) in the sub-basin with the ground water availability.

#### 9.4.1.4 Arkavathi sub-basin

In the Arkavathi sub-basin it is found that with the ground water availability considerations [refer Table 4.14.4], the maximum water deficit has reduced from (-205.15) MCM (-8.71%) to (-196.97) MCM (-8.1%) in the month of September and the minimum water deficit of (-24.55) MCM (-1.0%) in the sub-basin is reduced to (-17.63) MCM (0.70%) with the ground water considerations in the month of February. The amount of annual water deficit has reduced from (-799.19) MCM (-34.10%) to -712.56 MCM (-29.4%) in the sub-basin with the ground water availability considerations.

# 9.4.1.5 Middle Cauvery sub-basin

In the Middle Cauvery sub-basin it is found that with the ground water availability considerations [refer Table 4.14.5], the maximum water surplus in the sub-basin is increased from 24.14 MCM (1.1%) to 54.48 MCM (2.4%) in the month of September and the minimum water surplus in the sub-basin is increased from 1.08 MCM (0.01%) to 2.11 MCM (0.10%) in the month of July. The maximum water deficit has reduced from (-3.31) MCM (-0.2%) in the month of March to (-2.27) MCM (-0.1%) in the month of May and the minimum water deficit of (-1.63) MCM (-0.10%) in the sub-basin is reduced to (-1.28) MCM (-0.1%) with the ground water considerations in the month of June. The amount of annual surplus water has increased from (67.40) MCM (3.1%) to (268.94) MCM (12.10%) in the sub-basin with the ground water availability.

#### 9.4.1.6 Suvarnavathi sub-basin

In the Suvarnavathi sub-basin it is found that with the ground water availability

considerations [refer Table 4.14.6], the maximum water surplus in the sub-basin is increased from 6.52 MCM (0.9 %) to 6.84 MCM (9.11%) in the month of October and the minimum water surplus in the sub-basin is increased from 2.67 MCM (0.30%) to 2.83 MCM (0.50%) in the month of September. The maximum water deficit has reduced from (-17.01) MCM (-2.3%) in the month of July to (-6.52) MCM (-0.9%) in the month of January and the minimum water deficit of (-0.55) MCM (-0.1%) in the month of May in the sub-basin is reduced to (-0.70) MCM (-0.1%) with the ground water considerations in the month of May. The amount of annual water deficit has changed from (-80.00) MCM (-10.90%) to (-22.11) MCM (-2.90%) in the sub-basin with the ground water availability.

#### 9.4.1.7 Palar sub-basin

In the Palar sub-basin it is found that with the ground water availability considerations [refer Table 4.14.7], the maximum water surplus in the sub-basin is increased from 6.00 MCM (1.9 %) in the month of June to 10.05 MCM (2.8%) in the month of September and the minimum water surplus in the sub-basin is increased from 1.84 MCM (0.6%) in the month of October to 3.40 MCM (1.0%) in the month of August. The maximum water deficit has reduced from (-30.75) MCM (-9.5%) in the month of July to (-12.35) MCM (-3.5%) in the month of February and the minimum water deficit of (-0.59) MCM (-0.2%) in the sub-basin is reduced to (-0.36) MCM (-0.1%) with the ground water considerations in the month of May. The amount of annual water deficit has reduced from (-161.00) MCM (-50%) to (-28.49) MCM (-8.0 %) in the sub-basin with the ground water availability.

#### 9.4.1.8 Chinnar sub-basin

In the Chinnar sub-basin it is found that with the ground water availability

considerations [refer Table 4.14.8], the maximum water surplus in the sub-basin is increased from 6.00 MCM (1.9 %) in the month of June to 10.05 MCM (2.8%) in the month of September and the minimum water surplus in the sub-basin is increased from 1.84 MCM (0.60%) in the month of October to 3.40 MCM (1.0 %) in the month of August. The maximum water deficit has reduced from (-30.75) MCM (9.50%) in the month of July to (12.35) MCM (-3.50%) in the month of February and the minimum water deficit of (-0.59) MCM (-0.2%) in the sub-basin is reduced to (-0.36) MCM (-0.1%) with the ground water considerations in the month of May. The amount of annual water deficit has reduced from (-161) MCM (-50.00%) to (-28.49) MCM (-8.00%) in the sub-basin with the ground water availability.

#### 9.4.1.9 Bhavani sub-basin

In the Bhavani sub-basin it is found that with the ground water availability considerations [refer Table 4.14.9], the maximum water surplus in the sub-basin is increased from 98.80 MCM (3.5 %) in the month of November to 106.39 MCM (9.2%) in the month of October and the minimum water surplus in the sub-basin is increased from 23.26 MCM (1.30%) to 35.44 MCM (2.0%) in the month of December. The maximum water deficit has reduced from (-164.53) MCM (-5.8%) in the month of March to (-49.75) MCM (-4.3%) in the month of June and the minimum water deficit of (-8.84) MCM (-0.3%) in the sub-basin is reduced to (-11.19) MCM (-1.00%) with the ground water considerations in the month of September. The amount of annual water deficit has changed from (-424.9) MCM (-15.0%) to (-66.40) MCM (-5.70%) in the sub-basin, with the ground water considerations.

#### 9.4.1.10 Noyil sub-basin

In the Noyil sub-basin it is found that with the ground water availability

considerations [refer Table 4.14.10], the maximum water surplus in the sub-basin is increased from 106.39 MCM (9.2 %) to 105.91 MCM (8.7%) in the month of October and the minimum water surplus in the sub-basin is increased from 23.26 MCM (2.0%) to 23.46 MCM (1.9%) in the month of December. The maximum water deficit has reduced from (-49.75) MCM (-4.3%) to (-42.02) MCM (-3.4%) in the month of June and the minimum water deficit of (-11.19) MCM (-1.0%) in the sub-basin is reduced to (-10.23) MCM (-0.8%) with the ground water considerations in the month of September. The amount of annual water deficit has changed from (-66.40) MCM (-5.7%) to (-39.92) MCM (-3.3%) in the sub-basin with the ground water availability.

# 9.4.1.11 Amaravathi sub-basin

In the Amaravathi sub-basin it is found that with the ground water availability considerations [refer Table 4.14.11], the maximum water surplus in the sub-basin is increased from 189.79 MCM (7.1 %) to 190.15 MCM (6.9%) in the month of November and the minimum water surplus in the sub-basin is increased from 124.28 MCM (4.6%) to 125.29 MCM (4.61%) in the month of October. The maximum water deficit has reduced from (-207.29) MCM (-7.7%) to (-171.93) MCM (-6.2%) in the month of March and the minimum water deficit of (-40.31) MCM (-1.5%) in the sub-basin is reduced to (-19.87) MCM (-0.7%) with the ground water considerations in the month of September. The amount of annual water deficit has changed from (-746.90) MCM (-27.90%) to (-453.63) MCM (-16.5%) in the sub-basin with the ground water availability.

#### 9.4.1.12 Tirumanimuttar sub-basin

In the Tirumanimuttar sub-basin it is found that with the ground water

availability considerations [refer Table 4.14.12], the maximum water surplus in the sub-basin is increased from 267.48 MCM (7.3 %) to 301.08 MCM (7.9%) in the month of October and the minimum water surplus in the sub-basin is increased from 50.49 MCM (1.4%) to 79.69 MCM (2.1%) in the month of December. The maximum water deficit has reduced from (-147.29) MCM (-4.0%) to (-71.71) MCM (-1.9%) in the month of March and the minimum water deficit of (-37.17) MCM (-1.0%) in the sub-basin is reduced to (-18.26) MCM (-0.5%) with the ground water considerations in the month of January. The amount of annual water deficit has changed from (-225.54) MCM (-6.1%) to (-100.64) MCM (-2.7%) in the sub-basin with the ground water availability.

# 9.4.1.13 Ponnanai Ar sub-basin

In the Ponnanai Ar sub-basin it is found that with the ground water availability considerations [refer Table 4.14.13], the maximum water surplus in the sub-basin is increased from 43.78 MCM (4.5 %) to 69.70 MCM (6.3%) in the month of November and the minimum water surplus in the sub-basin is increased from 0.19 MCM (0.01%) in the month of February to 2.34 MCM (0.2%) in the month of April. The maximum water deficit has reduced from (-18.84) MCM (-1.9%) in the month of July to (-1.59) MCM (-0.2%) in the month of December. The sub-basin has become water surplus from water deficit on an annual basis due to consideration of ground water availability. The amount of annual water deficit has changed from (-13.74) MCM (-1.4%) to 216.89 MCM (19.70%) in the sub-basin with the ground water availability.

# 9.4.1.14 Upper Coleroon sub-basin

In the Upper Coleroon sub-basin it is found that with the ground water availability considerations [refer Table 4.14.14], the maximum water surplus in the sub-

basin is increased from 132.50 MCM (9.8 %) to 149.73 MCM (10.91%) in the month of November and the minimum water surplus in the sub-basin has changed from 4.80 MCM (0.4%) in the month of May to 0.86 MCM (0.06%) in the month of April. The maximum water deficit has reduced from (-69.07) MCM (-5.1%) to (-10.73) MCM (-0.78%) in the month of July and the minimum water deficit of (-2.8) MCM (-0.20%) in the month of June in the sub-basin is reduced to (-0.61) MCM (-0.04%) in the month of March. The amount of annual water deficit has changed from 86.64 MCM 6.4% to 358.44 MCM (26.11%) in the sub-basin with the ground water availability.

# 9.4.1.15 Lower Coleroon sub-basin

In the Lower Coleroon sub-basin it is found that with the ground water availability considerations [refer Table 4.14.15], the maximum water surplus in the sub-basin is increased from 46.01 MCM (3.6%) to 74.12 MCM (5.7%) in the month of September, and the minimum water surplus in the sub-basin is increased from 2.80 MCM (0.2%) to 2.87 MCM (0.2%) in the month of May. The amount of annual surplus water has changed from 222.2 MCM (17.2%) to 340.16 MCM (26.1%) in the sub-basin with the ground water availability.

# 9.4.1.16 Cauvery Delta sub-basin

In the Cauvery Delta sub-basin it is found that with the ground water availability considerations [refer Table 4.14.16], the maximum water surplus in the sub-basin is increased from 256.38 MCM (2.6 %) to 307.95 MCM (3.10%) in the month of September and the minimum water surplus in the sub-basin has changed from 10.45 MCM (0.11%) to 9.77 MCM (0.10%) in the month of May. The amount of annual surplus water has changed from 1203.1 MCM (12.10%) to 1413.26 MCM (14.10%) in the sub-basin with the ground water availability.

# 9.4.2 LP Model Studies for Conjunctive Water Resources Development for 75% Water Year Dependable Flow

The results of LP model for 75% water year dependable flow with 5800 MCM exports from Mettur reservoir to the sub-basins below Mettur are presented in Table 9.3 (for the objective function of maximization of water utilization with lumped irrigation).

Table 9.3: Sub-basin wise Annual Surplus/Deficit in Cauvery Basin from LP Model for 75% Water Year Dependable Flow

| Sl. No. | Name of sub-basin | With ground water (MCM) |
|---------|-------------------|-------------------------|
| (1)     | (2)               | (3)                     |
| 1       | Upper Cauvery     | -703.41                 |
| 2       | Kabini            | -172.39                 |
| 3       | Shimsha           | -1389.95                |
| 4       | Arkavathi         | -2121.66                |
| 5 .     | Middle Cauvery    | 1788.19                 |
| 6       | Suvarnavathi      | -634.41                 |
| 7       | Palar             | -170.06                 |
| 8 .     | Chinnar           | -213.07                 |
| 9       | Bhavani           | -1159.90                |
| 10      | Noyil             | -1058.10                |
| 11      | Amaravathi        | -1379.24                |
| 12      | Tirumanimuttar    | -2465.51                |
| 13      | Ponnanai Ar       | -420.10                 |
| 14      | Upper Coleroon    | -296.89                 |
| 15      | Lower Coleroon    | -506.27                 |
| 16      | Cauvery Delta     | -2541.36                |
| Total   |                   | -13444.12               |

The basic differences between water balance approach and the linear programming model approach are as follows:

In the water balance study, it is assumed that the total water resources available in a sub-basin are being utilized in the same sub-basin, except exports to other sub-basins. Whereas, in the linear programming model this is not the case, and the difference is that: (i) entire water resources are not being utilized in the same sub-basin, and (ii) there is an influence of reservoir storage, time wise variations in water availability and water use, reservoir spills, and variable evaporation losses with respect to time, etc.

The overall influence on the behavior of various sub-basins due to above factors is summarized below for 75% water year dependable flow with 5800 MCM of water export from Mettur to the sub-basins below Mettur:

- (1) From the linear programming results it is found that except Middle Cauvery sub-basin all the other sub-basins are water deficit. Following four types of monthly water deficit patterns are noticed, when the deficits are arranged in descending order.
  - (i) In the Suvarnavathi and Palar sub-basins, the decreasing pattern in the monthly percent deficits are found in the same months, except in the months of January and February.
  - (ii) In the Bhavani and Amaravathi sub-basins, the decreasing patterns in the monthly percent deficits are found in the same months, except in the months of January, February, June and September.
  - (iii) In the sub-basins of Upper Coleroon, Lower Coleroon and Cauvery

    Delta, the decreasing pattern in the monthly percent deficits are found in
    the same month, for all the months.

- (iv) For the remaining nine sub-basins there is no similarity, and have different monthly percent deficits patterns.
- (2) The Arkavathi sub-basin has the maximum percent deficit of 16% in the month of September, in the entire Cauvery river system, and the Upper Cauvery sub-basin has the minimum deficit of 0.001% in the month of May. Similarly, the Noyil and Arkavathi sub-basin have the maximum annual deficits of 87% and the Chinnar sub-basin has the minimum annual deficit of 8%.
- (3) As said earlier, Middle Cauvery sub-basin is the only water surplus sub-basin in the entire river system. In this sub-basin, the month of July has the mximum surplus of 15% and the month of May has the minimum surplus of 0.40%. There is a 81% surplus water availability annually in Middle Cauvery sub-basin.

The sub-basin wise monthly deficits in descending order computed from LP model for 75% water year dependable flows for the Cauvery basin are presented in Table 9.4, and the sub-basin wise observations are presented below. [Refer Table 9.4].

# 9.4.2.1 Upper Cauvery sub-basin

In the case of Upper Cauvery sub-basin, from the LP model results it is found that the maximum water deficit in the sub-basin of -139.96 MCM (-3.9%) in the month of October and the minimum water deficit of -5.01 MCM (-0.1%) in the month of April. The amount of annual deficit water is of -703 MCM (-19.5%) in the sub-basin.

#### 9.4.2.2 Kabini sub-basin

In the case of Kabini sub-basin, from the LP model results it is found that the maximum water deficit in the sub-basin of -164.94 MCM (-3.4 %) in the month of August and the minimum water deficit of -4.95 MCM (-0.1 %) in the month of

February. The amount of annual deficit water is of -625 MCM (-12.7%) in the sub-basin.

#### 9.5.2.3 Shimsha sub-basin

In the case of Shimsha sub-basin, from the LP model results it is observed that the maximum water deficit in the sub-basin of -389.48 MCM (-10.3%) in the month of January and the minimum water deficit of -28.56 MCM (-0.8 %) in the month of October. The amount of annual deficit water is of -2149 MCM (-56.9%) in the sub-basin.

# 9.5.2.4 Arkavathi sub-basin

In the case of Arkavathi sub-basin, it is found from the LP model results that the maximum water deficit in the sub-basin of -395.41 MCM (-16 %) in the month of September and the minimum water deficit of -96.50 MCM (-4%) in the month of April. The amount of annual deficit water is of -2122 MCM (-87%) in the sub-basin.

#### 9.4.2.5 Middle Cauvery sub-basin

In the case of Middle Cauvery sub-basin, from the LP model results it is found that the maximum water surplus in the sub-basin of 336.8 MCM (15%) in the month of July and the minimum water surplus of 9 MCM (0.4%) in the month of May. The amount of annual surplus water is of 1788 MCM (81%) in the sub-basin.

#### 9.4.2.6 Suvarnavathi sub-basin

In the case of Suvarnavathi sub-basin, from the LP model results it is found that the maximum water deficit in the sub-basin of -111.5 MCM (-15 %) in the month of July and the minimum water deficit of -5.56 MCM (-1%) in the month of May. The amount of annual deficit water is of -607 MCM (-82%) in the sub-basin.

#### 9.4.2.7 Palar sub-basin

In the case of Palar sub-basin, from the LP model results it is observed that the maximum water deficit in the sub-basin of -34.54 MCM (-11%) in the month of July and the minimum water deficit of -2.55 MCM (-1%) in the month of May. The amount of annual deficit water is of -186 MCM (-57%) in the sub-basin.

#### 9.4.2.8 Chinnar sub-basin

In the case of Chinnar sub-basin, from the LP model results it is observed that the maximum water deficit in the sub-basin of -30.58 MCM (-1.1%) in the month of March and the minimum water deficit of -6.10 MCM (-0.2%) in the month of August. The amount of annual deficit water is of -229 MCM (-8%) in the sub-basin.

#### 9.4.2.9 Bhavani sub-basin

From the LP model results in the case of Bhavani sub-basin, it is found that the maximum water deficit in the sub-basin of -101.73 MCM (-4%) in the month of July and the minimum water deficit of -2.99 MCM (-0.1%) in the month of November. The amount of annual deficit water is of -606 MCM (-21%) in the sub-basin.

#### 9.4.2.10 Novil sub-basin

From the LP model results in the case of Noyil sub-basin, it is found that the maximum water deficit in the sub-basin of -174.11 MCM (-14 %) in the month of June and the minimum water deficit of -38.90 MCM (-3%) in the month of November. The amount of annual deficit water is of -1064 MCM (-87%) in the sub-basin.

#### 9.4.2.11 Amaravathi sub-basin

In the case of Amaravathi sub-basin, from the LP model results it is found that the maximum water deficit in the sub-basin of -262.38 MCM (-10%) in the month of

July and the minimum water deficit of -8.63 MCM (-0.30%) in the month of November. The amount of annual deficit water is of -1506 MCM (-55%) in the subbasin.

#### 9.4.2.12 Tirumanimuttar sub-basin

In the case of Tirumanimuttar sub-basin, from the LP model results it is found that the maximum water deficit in the sub-basin of -458 MCM (-12%) in the month of March and the minimum water deficit of -309.41 MCM (-8%) in the month of January. The amount of annual deficit water is of -309 MCM (-8%) in the sub-basin.

#### 9.4.2.13 Ponnanai Ar sub-basin

In the case of Ponnanai Ar sub-basin, from the LP model results it is observed that the maximum water deficit in the sub-basin of -61.89 MCM (-6%) in the month of December and the minimum water deficit of -10.64 MCM (-1.0%) in the month of February. The amount of annual deficit water is of -395 MCM (-40%) in the sub-basin.

## 9.4.2.14 Upper Coleroon sub-basin

In the case of Upper Coleroon sub-basin, it is found from the LP model results that the maximum water deficit in the sub-basin of -112.36 MCM (-8.3%) in the month of August and the minimum water deficit of -1.13 MCM (-0.1%) in the month of May. The amount of annual deficit water is of -468 MCM (-34.7%) in the sub-basin.

#### 9.4.2.15 Lower Coleroon sub-basin

In the case of Lower Coleroon sub-basin, it is found from the LP model results that the maximum water deficit in the sub-basin of -145.60 MCM (-11.2 %) in the month of August and the minimum water deficit of -1.47 MCM (-0.1%) in the month of May. The amount of annual deficit water is of -606 MCM (-46.5%) in the sub-basin.

#### 9.4.2.16 Cauvery Delta sub-basin

In the case of Lower Coleroon sub-basin, from the LP model results it is found that the maximum water deficit in the sub-basin of -1345.44 MCM (-14%) in the month of August and the minimum water deficit of -13.59 MCM (-0.1%) in the month of May. The amount of annual deficit water is of -5600 MCM (-56%) in the sub-basin.

#### 9.4.2.17 Spills from sub-basins

The monthly spills over the year from the respective sub-basins in Cauvery basin obtained from Linear Programming model for 75% water year dependable flows with the 5800 MCM water exports from Mettur to the sub-basins below Mettur are presented in the Table 9.5.

The model results show the following pattern:

There may be sometimes shortages of water to meet the demands even though water is available within the sub-basins, but in the LP model the available water in various sub-basins is to be utilized optimally through the intra-basin water transfers over the Cauvery basin as a whole. Due to the consideration in the model of variability in the water availability and its use, with respect to space and time, there may be imbalance between the water needed and its availability; this at times may cause spills from reservoirs etc.

In Upper Cauvery sub-basin the spills occur during the months of June and August. In case of Kabini sub-basin there are no spills during the months of December to March but other months are having spills. In the case of Shimsha, Arkavathi, Palar, Amaravathi, Tirumanimuttar, Ponnanai Ar, Upper Coleroon, Lower Coleroon and Cauvery Delta sub-basis, the spills occurred in the every month during the year. In the Suvarnavathi sub-basin, no spill occurred during the month of May and remaining

months had spills. In the Bhavani and Noyil sub-basins spills occurred during through out the year except in the month of March. In the Cauvery Delta sub-basin spills do not occur during the months of January and February but other months are having spills.

### 9.4.2.18 Crop Planning

#### (i) General

The water availability is taken from the results of the LP model for 75% water year dependable flow with 5800 MCM of water exports from Mettur reservoir to the sub-basins below Mettur, for the objective function of maximization of annual water utilization. The irrigation was considered as lumped. The monthly diversions from reservoirs and ground water for lumped irrigation are obtained from LP model results. The cropping patterns is then studied for all the fifteen reservoirs (major projects). The optimal cropping patterns for the remaining areas not covered by these projects in their respective sub-basins, and other sub-basins, which did include any projects, were not determined. The cropping patterns are analyzed below keeping in mind (a) a number of paddy crops to be grown, (b) reducing the area for water extensive crops and (c) opting for higher revenue crops.

#### (ii) Objective function

Objective Function-Maximization of annual water utilization:

The crops at the reservoirs (major projects) [refer col. (4) in Tables 7.2.1 to 7.2.15], i.e., Mananthvady, Taraka, Upper Nugu, Mettur and Lower Bhavani do not occupy their entire respective proposed culturable command areas, with a minimum cropping intensity of 38% at Upper Nugu and a maximum cropping intensity of 97% at Mananthvady. The crops at the remaining projects do occupy their entire respective proposed culturable command areas, with 137% cropping intensity at Banasurasagar.

Objective function- Maximization of area to be irrigated:

The crops at reservoirs [refer col. (5) in Tables 7.2.1 to 7.2.15], i.e., Cauvery, Mananthvady, Taraka, Upper Nugu, Mettur and Lower Bhavani do not occupy their entire respective proposed culturable command areas, with a minimum cropping intensity of 54% at Upper Nugu and a maximum cropping intensity of 97% at Mananthvady. The crops at the remaining projects do occupy their entire respective proposed culturable command areas with 147% cropping intensity at Banasurasagar.

Objective function- Maximization of annual food production:

The crops at all the reservoirs [refer col. (6) in Tables 7.2.1 to 7.2.15], except Banasursagar and Sagardoddakere, do not occupy their entire respective proposed culturable command areas with a minimum cropping intensity of 53% at Mettur and a maximum cropping intensity of 86% at Mananthvady. The cropping intensities at Banasurasagar and Sagardoddakere are 164% and 273%, respectively. This objective function is the most sensitive in terms of cropping intensity.

Objective function- Maximization of annual benefits from crops (without minimum area for food requirements):

The crops at the reservoirs [refer col. (7) in Tables 7.2.1 to 7.2.15], i.e., Taraka, Upper Nugu, Mettur and Lower Bhavani do not occupy their entire respective proposed culturable command areas, with a minimum cropping intensity of 54% at Upper Nugu and a maximum cropping intensity of 91% at Taraka and Mettur. The crops at the remaining projects do occupy their entire respective proposed culturable command areas, with 135% cropping intensity at Banasurasagar.

Objective function- Maximization of annual benefits from crops (with minimum area for food requirements):

The crops at reservoirs [refer col. (8) in Tables 7.2.1 to 7.2.15], i.e., Mananthvady, Upper Nugu, Nugu and Amaravathi do not occupy their entire respective proposed culturable command areas, with a minimum cropping intensity of 52% at Mananthvady and a maximum cropping intensity of 73% at Nugu. The crops at the remaining projects do occupy their entire respective proposed culturable command areas, with more than 100% cropping intensities.

#### (iii) Water extensive crops

Except at Yagachi, Banasursagar, Mananthvady, Taraka, Upper Nugu and Mettur reservoirs, at other reservoirs, the water extensive crops, i.e., Sugarcane, Kharif Paddy and Rabi Paddy, almost acquire their respective proposed areas, for both the objective functions (i.e., maximization of annual water utilization, and maximization of area to be irrigated annually).

The variations among these crops are as follows:

Sugarcane: For the objective function of maximization of annual water utilization, this crop has cropping intensities of 99%, 2%, 99% and 0% at Yagachi, Banasursagar, Taraka and Upper Nugu, respectively.

Kharif Paddy: For the objective function of maximization of annual water utilization, this crop has cropping intensities of 78%, 41% and 36% at Mananthvady, Taraka and Upper Nugu, respectively.

Rabi Paddy: For the objective function of maximization of annual water utilization, this crop has cropping intensities of only 75%, 97% and 0% at Banasurasagar, Taraka, Upper Nugu and Mettur, respectively.

For the objective function of maximization of area to be irrigated annually, the behavior of these three crops is almost same as found for the objective function of maximization of annual water utilization, with minor variations.

#### (iv) Number of paddy crops to be grown

The pattern discussed below is for number of Paddy crops to be grown, obtained for the objective functions, i.e., maximization of annual water utilization and maximization of area to be irrigated annually.

- (a) Kharif Paddy: At Taraka and Upper Nugu reservoirs it is possible to cultivate only about 36% to 41% of their respective proposed crop areas. Similarly, at Mananthvady about 78% of the proposed crop areas can be cultivated. And at other reservoirs, it is possible to cultivate with full potential the Kharif Paddy.
- (b) Rabi Paddy: As far as the number of Paddy crops to be grown is concerned, it is not possible to cultivate Rabi Paddy at Mettur reservoir. At Banasursagar it is only possible to cultivate 75% of the proposed crop area. And at other reservoirs it is possible to cultivate with full potential the Rabi Paddy.

# (v) Imports / Exports of food

Except at Yagachi and Upper Nugu reservoirs, at other reservoirs the crop productions to meet minimum requirements of the agricultural population are fulfilled. At Yagachi and Upper Nugu reservoirs, the production of groundnut crop is not sufficient to fulfill the food requirements of the agricultural population at these reservoirs. The annual quantity of groundnut to be imported for these two projects works out to 24.12 MT and the annual quantities of other food grains exports from the projects are as follows:

Paddy - 749 MT, Jowar - 1159 MT, Ragi - 531 MT, Pulses - 483 MT, Fruits and Vegetables-14066 MT and Groundnut -541 MT.

#### (vi) High benefit crops

The high benefit crops like Sugarcane, Cotton, Tobacco, and Coconut are occupying their respective areas at all the reservoirs, except Sugarcane and Coconut at Banasurasagar and Upper Nugu reservoirs. The areas occupyied for Sugarcane and Coconut at Banasurasagar are 2% and 0%, respectively, and at Upper Nugu reservoir the areas being occupied for Sugarcane and Coconut are nil for both the crops.

# (vii) Most affected reservoir

Upper Nugu reservoir is the most affected in terms of crop area occupation (i.e., for Kharif Jowar, Kharif Ragi, Rabi Paddy, Pulses, Fruits and Vegetables, Groundnut, and Coconut) for both the objective functions, i.e., maximization of water utilization and maximization of area to be irrigated.

#### 9.4.2.19 Hydropower Generation

During a normal year at Manathvady reservoir about 377 MU (1 MU = 10<sup>6</sup> KWhr) of energy would be generated annually as against 817 MU as per the project proposal. Similarly, at Banasurasagar reservoir about 332 MU of energy would be generated annually as against 406 MU as per the project proposal. At Kabini and Mettur the generated and the proposed values are 769 MU and 98 MU, and 196 and 240 MU, respectively.

# 9.4.3 Water Utilization Factors

The computed monthly and annual water utilization factors from water balance study (conventional method) with 12712 MCM exports from Mettur reservoir and from LP model results with 5800 MCM water exports from Mettur reservoir, to the subbasins below Mettur, for 75% water year dependable flows are presented in Table 9.6

and 9.7, respectively. The following are the observations:

From the water balance studies it is found that except at Lower Coleroon and Cauvery Delta sub-basins in all other sub-basins, a maximum monthly water utilization factor of 1.0 (i.e., all the water demands are met from the available water in that month) is attained in different months, for both without and with ground water considerations. Whereas, at Amaravathi sub-basin a minimum of about 0.25 monthly water utilization factor in the month of November is attained.

The minimum monthly water utilization factors from water balance, and the annual water utilization factor from LP model studies are given below for each sub-basin.

As per the water balance studies, in the case of Upper Cauvery sub-basin, minimum monthly utilization factors of 0.36 and 0.71 for without and with ground water considerations are obtained, respectively. The annual water utilization factor in water balance studies is 0.96 for both without and with ground water considerations. From LP model the annual water utilization factor is 0.41 (see col.8 of Table 9.7). The difference is because in the water balance study, it was not possible to consider, the arial variability and distribution of the surface and ground water available and its availability in the basin, with respect to the locations of the various reservoirs and water use points.

The Kabini sub-basin has a minimum monthly utilization factor of 0.67 for both without and with ground water considerations. The annual water utilization factors in water balance studies are 1.00 and 0.98 for without and with ground water considerations. And as per LP model the annual utilization factor is 0.73.

As per the water balance studies, in the case of Shimsha sub-basin, minimum monthly utilization factors of 0.26 and 0.27 for without and with ground water considerations are obtained, respectively. The annual water utilization factors in water balance studies are 0.96 and 0.86 for without and with ground water considerations. From LP model the annual water utilization factor is 0.35 (see col.8 of Table 9.7).

As per the water balance studies, in the case of Arkavathi sub-basin, minimum monthly utilization factors of 1.00 for both without and with ground water considerations are obtained. The annual water utilization factor in water balance studies is 1.00 for both without and with ground water considerations. From LP model the annual water utilization factor is 0.30 (see col.8 of Table 9.7).

In the case of Middle Cauvery sub-basin, as per the water balance studies, minimum monthly utilization factors of 0.80 and 0.78 for without and with ground water considerations are obtained, respectively. The annual water utilization factors in water balance studies are 0.97 and 0.89 for without and with ground water considerations. From LP model the annual water utilization factor is 0.77 (see col.8 of Table 9.7).

As per the water balance studies, in the case of Suvarnavathi sub-basin, minimum monthly utilization factors of 0.72 and 0.73 for without and with ground water considerations are obtained, respectively. The annual water utilization factor in water balance studies is 1.00 for both without and with ground water considerations. From LP model the annual water utilization factor is 0.2 (see col.8 of Table 9.7).

In the case of Palar sub-basin, as per the water balance studies, minimum monthly utilization factors of 0.84 and 0.77 for without and with ground water considerations are obtained, respectively. The annual water utilization factor in water balance studies is 1.00 for both without and with ground water considerations. From LP model the annual water utilization factor is 0.60 (see col.8 of Table 9.7).

Chinnar sub-basin has a minimum monthly utilization factor of 1.00 for both without and with ground water considerations. The annual water utilization factor in water balance studies is 1.00 for both without and with ground water considerations. From LP model the annual water utilization factor is 1.00 (see col.8 of Table 9.7).

As per the water balance studies, in the case of Bhavani sub-basin, minimum monthly utilization factors of 0.65 for both without and with ground water considerations are obtained, respectively. The annual water utilization factor in water balance studies is 1.00 for both without and with ground water considerations. From LP model the annual water utilization factor is 0.52 (see col.8 of Table 9.7).

In the case of Amaravathi sub-basin, As per the water balance studies, minimum monthly utilization factors of 0.24 and 0.25 for without and with ground water considerations are obtained, respectively. The annual water utilization factor in water balance studies is 1.00 for both without and with ground water considerations. From LP model the annual water utilization factor is 0.62 (see col.8 of Table 9.7).

As per the water balance studies, in the case of Tirumanimuttar sub-basin, minimum monthly utilization factors of 0.51 and 0.58 for without and with ground water considerations are obtained, respectively. The annual water utilization factors in water balance studies are 1.00 and 0.94 for without and with ground water considerations, respectively. From LP model the annual water utilization factor is 0.36 (see col.8 of Table 9.7).

As per the water balance studies, in the case of Ponnanai Ar sub-basin, minimum monthly utilization factors of 0.70 and 0.60 for without and with ground water considerations are obtained, respectively. The annual water utilization factor in water balance studies are 1.00 and 0.82 for without and with ground water considerations respectively. From LP model the annual water utilization factor is 0.52 (see col.8 of Table 9.7).

In the case of Upper Coleroon sub-basin, As per the water balance studies, minimum monthly utilization factors of 0.53 and 0.48 for without and with ground water considerations are obtained, respectively. The annual water utilization factors in

water balance studies are 0.94 and 0.79 both without and with ground water considerations, respectively. From LP model the annual water utilization factor is 0.63 (see col.8 of Table 9.7).

As per the water balance studies, in the case of Lower Coleroon sub-basin, minimum monthly utilization factors of 0.69 and 0.65 for without and with ground water considerations are obtained, respectively. The annual water utilization factors in water balance studies are 0.85 and 0.79 for without and with ground water considerations. From LP model the annual water utilization factor is 0.50 (see col.8 of Table 9.7).

As per the water balance studies, in the case of Cauvery Delta sub-basin, minimum monthly utilization factors of 0.77 and 0.76 for without and with ground water considerations are obtained, respectively. The annual water utilization factors in water balance studies are 0.89 and 0.88 for without and with ground water considerations. From LP model the annual water utilization factor is 0.40 (see col.8 of Table 9.7).

# 9.4.4 Comparison of Total Annual Balance from Water Balance and LP Model Studies

While comparing the total annual water balances (refer Table 9.8), obtained from monthly water balance and LP model studies, for the 75 % water year dependable flow with consideration of ground water (when exports from Mettur reservoir to the sub-basins below Mettur in water balance is 12712 MCM and in LP model it is 5800 MCM), the following observations are made:

In the case of Upper Cauvery sub-basin, from water balance studies it is found that the sub-basin is surplus in water by 286.45 MCM (4.48%), while from LP model studies it is seen that there is a water deficit of -703.41 MCM (-11.01%).

In Kabini sub-basin from water balance studies, it is found that the sub-basin is surplus in water by 107.62 MCM (1.99%), while from LP model studies it is seen that there is a water deficit of -172.40 MCM (-3.47%).

In the case of Shimsha sub-basin, it is observed from water balance studies that, the sub-basin is surplus in water by 640.15 MCM (16.55%), while from LP model studies it is seen that there is a water deficit of -1389.95 MCM (-35.94%).

In the case of Arkavathi sub-basin, from water balance studies it is found that, the sub-basin is deficit in water by -712.56 MCM (-29.35%), while from LP model studies it is seen that there is a water deficit of -2121.66 MCM (-87.38%).

In the case of Middle Cauvery sub-basin, from water balance studies, it is found that the sub-basin is surplus in water by 268.94 MCM (12.11%), while from LP model studies it is seen that there is a water surplus of 1788.15 MCM (80.51%).

In the case of Suvarnavathi sub-basin, from water balance studies it is found that, the sub-basin is deficit in water by -22.11 MCM (-2.88%), while from LP studies it is seen that there is a water deficit of -634.41 MCM (-82.71%).

In the case of Palar sub-basin, from water balance studies it is found that, the sub-basin is deficit in water by -28.49 MCM (-7.98%), while from LP model studies it is seen that there is a water deficit of -170.06 MCM (-47.64%).

In the case of Chinnar sub-basin, from water balance studies it is observed that, the sub-basin is deficit in water by -12932.21 MCM (-78.01%), while from LP studies it is seen that there is a water deficit by -213.00 MCM (-1.28%).

In the case of Bhavani sub-basin, from water balance studies it is found that, the sub-basin is deficit in water by -247.39 MCM (-8.60%), while from LP studies it is seen that there is a water deficit of -1159.90 MCM (-40.30%).

In the case of Noyil sub-basin, it is found from water balance studies that, the

sub-basin is water deficit by -39.92 MCM (-3.27%), while from LP studies it is seen that there is a water deficit by -1058.10 MCM (-86.66%).

In the case of Amaravathi sub-basin, from water balance studies it is found that, the sub-basin is deficit in water by -453.63 MCM (-16.48%), while from LP studies it is seen that there is a water deficit by -1379.24 MCM (-50.10%).

In the case of Tirumanimuttar sub-basin, from water balance studies it is seen that, the sub-basin is surplus in water by 100.64 MCM (2.65%), while from LP studies it is seen that there is a water deficit by -2465.51 MCM (-65.02%).

In the case of Ponnanai Ar sub-basin, from water balance studies it is observed that, the sub-basin is surplus in water by 188.17 MCM (18.72%), while from LP studies it is seen that there is a water deficit of -420.10 MCM (-41.80%).

In the case of Upper Coleroon sub-basin, from water balance studies it is found that, the sub-basin is surplus in water by 334.44 MCM (24.36%), while from LP studies it is seen that there is a water deficit by -296.89 MCM (-21.62%).

In the case of Lower Coleroon sub-basin, from water balance studies it is observed that, the sub-basin is surplus in water by 340.16 MCM (26.09%), while from LP studies it is seen that there is a water deficit by -506.27 MCM (-38.82%).

In the case of Cauvery Delta sub-basin, from water balance studies it is found that,, the sub-basin is surplus in water by 1413.26 MCM (14.12%), while from LP studies it is seen that there is a deficit by -2541.36 MCM (-25.39%).

In the case of Cauvery basin as a whole, from water balance studies it is found that, the Cauvery basin is deficit in water by -10586.00 MCM (-17.95%), while from LP studies it is seen that there is a water deficit of -13444.12 MCM (-22.79%).

From the above discussion for the monthly water balance on annual basis, it is seen that, the Cauvery Delta sub-basin has the maximum surplus of 1413.26 MCM

(14.12%) and the Tirumanimuttar sub-basin has the minimum surplus of 100.64 MCM (2.64%). Whereas, the Chinnar sub-basin has the maximum deficit of -12932.21 MCM (-78.01%) and the Suvarnavathi sub-basin has the minimum deficit of -22.11 MCM (-2.88%).

Similarly, from the LP model results, it is seen that, only the Middle Cauvery sub-basin has the surplus of 1788.15 MCM (80.51%). Whereas, the Cauvery Delta sub-basin has the maximum deficit of -2541.36 MCM (-25.31%) and the Palar sub-basin has the minimum deficit of -170.06 MCM (-47.64%).

#### 9.4.5 Intra-basin Water Exports Within Sub-basins

As per LP model results all the proposed intra-basin water exports except from Kabini project, are possible. Only 76% of proposed as per NWDA reports, intra-basin exports are possible from the Kabini project to the surrounding sub-basins for 75% water year dependable flow after fulfilling its own irrigation and water supply requirements within the sub-basin for 5800 MCM water exports from Mettur to the sub-basins below Mettur. As per the LP model results for 75%, 50%, 90%, and 100% water year dependable flows, the maximum water exports possible to the sub-basins below Mettur are 7200 MCM, 7800 MCM, 6900 MCM, and 6700 MCM, respectively, after fulfilling the irrigation and water supply demands of respective sub-basins.

# 9.5 NEED OF INTER-BASIN IMPORTS OF WATER FROM OTHER RIVER BASIN/BASINS

The Cauvery basin is always short of water for all the water year dependable flow studied, as determined from the monthly water balance computation on an annual basis. The inter-basin imports required from the other river basin/basins river to the Cauvery river basin for various water years dependable flows, obtained from water balance studies are given in Table 9.9.

Table 9.9: Inter-basin Imports Required from Other River Basin / Basins as per Water Balance Studies

| Sl.<br>No. | Water span dependable flow      | Without ground water | With ground water |
|------------|---------------------------------|----------------------|-------------------|
|            | Water year dependable flow      | (MCM)                | (MCM)             |
| 1          | 75% water year dependable flow  | 14434                | 10586             |
| 2          | 50% water year dependable flow  | 13572                | 9859              |
| 3          | 90% water year dependable flow  | 16896                | 13364             |
| 4          | 100% water year dependable flow | 20300                | 17719             |

Note: Exports from Mettur Reservoir is 12712 MCM,

The inter-basin imports required from the other river basin/basins river to the Cauvery river basin for various water years dependable flows, obtained from LP model are given in Table 9.10.

Table 9.10: Inter-basin Imports Required from Other River Basin / Basins as per LP Model Studies

| Sì. No. | W-to-to-down doble form         | With ground water consideration |  |
|---------|---------------------------------|---------------------------------|--|
|         | Water year dependable flow      | (MCM)                           |  |
| 1       | 75% water year dependable flow  | 13444.12                        |  |
| . 2     | 50% water year dependable flow  | 12468.91                        |  |
| 3       | 90% water year dependable flow  | 15888.95                        |  |
| 4       | 100% water year dependable flow | 18853.4                         |  |

Note: Exports from Mettur Reservoir is 5800 MCM.

In the water balance studies of the NWDA the maximum proposed exports from Mettur reservoir to the sub-basins below Mettur is shown as 12712 MCM for normal

year, i.e. for 75% water year dependable flow, while as per the LP model, for 75%, 50%, 90% and 100% water year dependable flows these are 7200 MCM, 7800 MCM, 6900 MCM, and 6700 MCM, respectively, as given in Section 9.4.4.

#### 9.6 CONCLUSIONS

The conclusions drawn from the study on "Optimal Water Utilization and Intrabasin Water Transfers in Cauvery Basin, India," are stated crisply based on the findings of the work done as below:

- (1) A true estimate of water balance of a large river basin can only be achieved, if viewed altogether from a different perspective, unlike the conventional method usually carried out on an annual basis. The basin's variability with respect to the time and space of various parameters, in meeting various water demands and influencing the water balance, i.e. availability of surface and ground waters, use of water, effect of reservoir storages, etc., should be considered and their impact on the water balance should be looked into. Incorporating the variability in space of these parameters, however, is not possible in the conventional method of water balance. In the present study, therefore, only the time variability of the parameters was accounted for in the water balance study of Cauvery river basin. The water balance studies carried out for the Cauvery river system, with and without ground water availability considerations, do provide a clear picture of the monthly variations in the supply and demand in the basin.
- (2) A water balance study of a river basin is unable to provide us with all the information, what is needed in planning for the development of its water

resources. This is one thing that the water balance study of a river basin, does not take into account for the impact of the space variability of various parameters on its water balance, but the optimal use of its water resources is another thing. This necessitated the need of adopting a linear programming based optimization model for the solution of the optimal utilization of Cauvery river waters, a model which can easily incorporate the above two aspects of planning into the model and can also handle a large size optimization problem. The affects of the time and aerial variability in the basin, of the supply and demand, have been clearly brought out by the optimization model.

- (3) The water balance study showed that, with ground water availability considerations, the Upper Cauvery, Kabini, Tirumanimuttar and Ponnanai Ar sub-basins become water surplus from water deficit, during normal and good water years (i.e., for the flows from the 75% water year dependable flow upwards up to the years of highest flows).
- (4) All the sixteen sub-basins in the Cauvery river system, except Middle Cauvery sub-basin, are found short of water during normal and bad water years (i.e., for the flows from the 75% water year dependable flow downwards up to the years of lowest flows), as determined from the linear programming model, whereas the Noyil and Arkavathi sub-basins suffer the most from water deficits, and the Chinnar sub-basin the least.
- (5) The Kabini sub-basin is not able to fulfill its intra-basin water exports requirements completely during normal and bad water years, as determined

from linear programming model.

- (reservoir releases) possible from the Mettur reservoir to the other sub-basins below Mettur for 75%, 50%, 90% and 100% water year dependable flows are 7200 MCM, 7800 MCM, 6900 MCM, and 6700 MCM, respectively, while in the water balance studies of the NWDA the maximum proposed exports from Mettur reservoir to the sub-basins below Mettur is shown as 12712 MCM for a normal water year.
- As per LP model results it is found, that the water share ratios for above and below Mettur for a normal water year with 5800 MCM exports from Mettur reservoir to the sub-basins below Mettur, and other water years, i.e., a water surplus year (50% water year dependable flow), a water deficit year (90% water year dependable flow) and a critical water year (100% water year dependable flow) are in the proportion of 0.98:1.07:0.79:0.72, respectively.
- (8) From the LP model results it is observed that during a normal water year (i.e., the 75% water year dependable flow) various crops would follow the following pattern:
  - (i) The water extensive crops, i.e., Sugarcane, Kharif Paddy and Rabi Paddy would not completely acquire their respective crops areas at Yagachi, Banasurasagar, Mananthvady, Taraka, Upper Nugu and Nugu reservoirs.
  - (ii) Except at Mananthvady, Taraka and Upper Nugu it would be

possible to cultivate with full potential the Kharif Paddy. Similarly, except at Banasurasagar and Mettur it would be possible to cultivate with full potential the Rabi Paddy.

- (iii) Yagachi and Upper Nugu reservoirs would need import of Sugarcane.
- (iv) The high benefit crops, i.e., Sugarcane and Coconut would acquire very little crop areas at Banasurasagar and Upper Nugu reservoirs.
- (v) Upper Nugu reservoir is the most affected reservoir in terms of the crop area occupation.
- (9) The water balance study revealed that during a normal water year, except at Lower Coleroon and Cauvery Delta sub-basins a maximum monthly water utilization factor of 1.00 would be achieved in different months, whereas, at Amaravathi sub-basin a minimum of about 0.25 monthly water utilization factor in the month of November would be achieved both with and without groundwater considerations.

From the linear programming results, the maximum annual water utilization factor is 1 at Chinnar sub-basin and the minimum annual water utilization factor 0.19 at Noyil sub-basin.

- (10) Shimsha, Arkavathi, Palar, Amaravathi, Tirumanimuttar, Ponnanai Ar, Upper Coleroon, Lower Coleroon and Cauvery Delta sub-basins, would spill, in all the months during a normal water year.
- (11) From the linear programming model results, it is found that during a normal

water year, the annual energy production in the system would be 1675 MU. At Kabini reservoir the annual energy generation would be more than the proposed.

- During a normal water year (i.e., the 75% water year dependable flow) about 18.14% of the total annual water demands, i.e., an amount of water equal to the Cauvery basin's annual water needs of 58978 MCM, may need to be imported from the other river basin/basins, as per the water balance studies carried out for conjunctive use development in the basin. The inter-basin water importing needs during a normal and other water years, i.e., a water surplus year, a water deficit year and a critical water year are in the ratios of 1.00:0.93:1.26:1.67, respectively.
- MCM water export from Mettur reservoir to the sub-basins below Mettur during a normal water year and other water years, i.e., a water surplus year, water deficit year and a critical water deficit year are in the ratios of 1.00:0.92:1.18:1.40, respectively.

# 9.7 SCOPE FOR FUTURE STUDY

The Supreme Court of India has recently given directives to the Government of India for interlinking the major rivers of the Himalayan and Peninsular regions for transfer of waters from the water surplus basins to the water deficit basins to reduce the natural imbalance of the water availability in the country. The studies on various interbasin water transfers are carried out, usually on the basis of the annual water balance of all the sub-basins lying in the respective major river basins involved, to determine the

amount of water available and to identify the water surplus and water deficit basins. The annual water balance studies carried out do not take into account: (i) the areal variability and distribution of the water available and its use in the basin, with respect to the locations of the various reservoirs and water use points, (ii) the time wise variability and distribution in the water availability with respect to the yearly and the within the year time periods, and (iii) the availability and use of the ground water. Therefore, for the proper planning and optimal water use, it may be now essential that before the decisions are arrived at for the final implementation of the reservoir projects etc., involved in these proposed inter-basin water transfers, the yield analysis of the various reservoirs in the entire large integrated river system should be carried out using systems analysis techniques. For this purpose, the following may be further carried out: (i) initially the multireservoir multiyield model for the yield analysis of single and multipurpose reservoirs developed by Dahe and Srivastava (2002) can be applied for preliminary screening, to screen a few most attractive alternatives among all the techno-feasible water transfer alternatives possible, within the framework of the existing agreements and the tribunal awards related to the transboundary river water disputes among the various river basins involved, regarding sharing of the river waters among the respective co-basin states, and then analyze these most attractive alternatives selected earlier, by a detailed simulation model, and (ii) the use of ground water should be also included in these studies. If the above considerations are incorporated further into the studies of the inter-basin water transfers among the major river basins, the purpose is not alone to ascertain, precisely and accurately the extent of the amount of basins, and the amount of the shortfall of water in a water deficit basin and the need to import water from the water surplus basins, which will also establish if there is a need of the intra-basin water transfers among the various reservoirs and water use points of the sub-basins lying in a major river basin.

| Note:      | (1) Utilization fact | (1) Utilization factor calculated in water balance studi | alance stud | ies is the | es is the ratio between the water utilization (demands) and the amount of water availability | ween the | water un | ilization | (demano    | ls) and th | ie amoun    | it of water | r availab | ility |          |

(2) Further in the water balance studies it is assumed that the available water in a sub-basin is to be utilized first within the sub-basin, and then to be exported (1) Utilization factor calculated in water balance studies is the ratio between the water utilization (demands) and the amount of water availability to other sub-basins if surplus, as water balance are done independent of other sub-basins. (3) Exports from Mettur reservoir to the sub-basins below Mettur is 12712 MCMC

Table 9.7: Computed Annual Water Utilization Factors from LP Model Results with 5800 MCM Water Exports from Mettur to the Sub-basins Below Mettur for 75% Water Year Dependable Flows

Note: (1) sw = Surface water.

sw + imp = Surface water + imports.

sw + imp + swr = Surface water + imports + regenerations from surface water use.

g.w. = Ground water

gw+gwr = Ground water + regenerations from geround water use

sw+imp+swr+gw+gwr = Surfacw water + imports + regenerations from surface water use + ground water + regenerations from ground water use

- (2) The utilization factors calculated from LP model, where, the utilization factor is less than one, the surplus water is available; however, when the utilization factor is equal to one, it means the demands are not completely met with the following interpretations:
  - (i) the available water is less than the demands, and (ii) the available water is more than the demands and a part of available water is being diverted optimally to downstream sub-basins. This shows the impact of storages and locations on water utilization.

This is because, the entire river system is considered as one, unlike in water balance studies where each sub-basin was considered independently.

Table 9.8: Comparison of Total Annual Water Balance from Water Balance and LP Model Studies

## THE LP LINDO FORM OF EQUATIONS

#### IV.1 GENERAL

In this research work the readily available LINDO SOFTWARE package of version 6.1, which is released in August 2001, by LINDO Systems, inc, 1415 North Dayton st. Chicago, IL, USA, having the maximum capacity of 4000 constraints and 8000 variables with 100 integer variables and 2000000 non zeros, was used to solve the LP model, as there are many constraints and variables to handle such a big problem.

The LP LINDO format for equations is prepared for running the model by writing the equations in the required form of equations for LINDO software version 6.1 2001 as given below.

The sample LINDO form of equation as given below is prepared for Kabini reservoir in Kabini sub-basin.

The nomenclature was done by using the first letter of name of the site, first two letters of the sub-basin name and maximum five letters of a variable because the LINDO software version 6.1 2001 takes maximum eight letter for the nomenclature for the model writing and running on it for getting the feasible solution of the problem.

The projectwise and vaiablewise notations used in the model running on the LINDO software are given in Tables 6.7 and 6.8, respectively.

For running and solving the Linear Programming model by using, LINDO SOFTWARE, the first objective function, i.e., to maximize the annual water utilization and the constraint equations are written in the following form of equations:

#### IV.2 OBJECTIVE FUNCTION

To maximize the total annual reservoir diversion (Annual water utilization) from a multipurpose reservoir for irrigation, domestic, industrial, hydropower, and environmental site i, for the proposed river basin system can be calculated as follows.

Let, KKB, i.e., K = Kabini project

and KB = Kabini Sub-Basin

#### Equation 5.2.1-a

Original equation 5.2.1-a is given below:

$$\begin{aligned} \text{Max.} Z &= \sum_{j=1}^{N} \sum_{i,j} \text{Ir}_{i,j} \\ \text{j = 1} & i = 1 \end{aligned} \qquad \begin{aligned} &\text{for lumped irrigation model } 5.2.1\text{-a} \\ &\text{for each i and i.} \end{aligned}$$

LINDO form of equation of 5.2.1-a is as follows:

MAX KKBIRD

#### IV.3 CONSTRAINTS

# IV.3.1 Reservoir Continuity Equation Constraints

#### **Equation 5.3.1.1**

The original equation 5.3.1.1 is as follows:

$$\begin{split} &K_{i,j,t}^{'} * S_{i,j,t} = S_{i,j,t-1} + I_{i,j,t} + F_{i,j,t} + \sum (\psi_{i,j,t}^{q,j_t} * TI_{i,j}^{q,j_t}) + \\ &\sum_{p=1}^{X_{i,j}} K_{p_i,j,t}^{''} (*\psi_{i,j,p}^{q,j_t} * OI_{i,j,p}^{q,j_t}) + P_{i,j,t} + I_{i,j,t} - O_{i,j,t}^{m} - O_{i,j,t} - O_{i,j,t}^{\text{Se}} \\ &- (\alpha_{i,j,t} * Iu_{i,j}^{*} + \beta_{i,j,t} * Iu_{i,j}^{m,hs}) + (\alpha_{i,j,t}^{*} * \alpha_{i,j,t} * Iu_{i,j}^{r}) + (\beta_{i,j,t}^{*} * \beta_{i,j,t} Iu_{i,j}^{m}) \\ &- \sum (\omega_{i,j}^{q,j_s} * TE_{i,j}^{q,j_s}) \end{split}$$

Rearranged equation 5.3.1.1 is as follows:

$$\begin{split} &K_{i,j,t}^{'} * S_{i,j,t} - S_{i,j,t+1} + O_{i,j,t} - F_{i,j,t} - P_{i,j,t} - \overline{I}_{i,j,t} + O_{i,j,t}^{se} \\ &- (\psi_{i,j,t}^{q,j_1} * TI_{i,j}^{q,j_1}) + \sum (\omega_{i,j,t}^{q,j_2} * TE_{i,j}^{q,j_2}) - + \alpha_{i,j,t} * \overline{Iu}_{i,j}^{rs} + \beta_{i,j,t} * \overline{Iu}_{i,j}^{mhs} \\ &- (\alpha_{i,j,t}^{"} * \alpha_{i,j,t} * \overline{Iu}_{i,j}^{r}) - (\beta_{i,j,t}^{"} * \beta_{i,j,t} * \overline{Iu}_{i,j}^{m}) + O_{i,j,t}^{m} - I_{i,j,t} = 0 \end{split}$$

LINDO form of equation of 5.3.1.1 is as follows:

$$\begin{split} &K_{i,j,t}^{+}*KKBSt-KKBS0+KKBOt-KKBFt-KKBPt-KKB \dot{I}t+kk@O_{Se}\\ &-\psi_{i,j,t}^{q,j_{1}}*KKBTI+\omega_{i,j,t}^{q,j_{2}}*KKBKUTTE+\alpha_{i,j,t}*KKBIURS+\\ &\beta_{i,j,t}KKBIUMHS-(\alpha_{i,j,t}^{+}*\alpha_{i,j,t})KKBIUR-(\beta_{i,j,t}^{+}*\beta_{i,j,t})KKBIUM\\ &+KKBOMt-KKBIt=0 \end{split}$$

#### **Equation 5.3.1.8**

Original equation 5.3.1.8 is as follows:

$$F_{i,j,t} = \sum_{w=1}^{z_{i,j}} \left[ Sp_{w,j,t} + (K_{w,j,t}^{"} * K_{w,j,t} * Ir_{w,j}^{'}) + (\beta_{w,j,t}^{"} * \beta_{w,j,t} * Ws_{w,j}^{'}) + \delta_{w,j,t}^{"} * O_{w,j,t}^{m} \right] + (\alpha_{i,j,t}^{"} * \alpha_{i,j,t} * Iu_{i,j}^{r}) + (\beta_{i,j,t}^{"} * \beta_{i,j,t} * Iu_{i,j}^{m})$$

Rearranged equation 5.3.1.8 is as follows:

$$\begin{split} F_{i,j,t} &= \sum_{w=1}^{Z_{i}} \left[ Sp_{w,j,t} + (K_{w,j,t}^{"} * K_{w,j,t} * Ir_{w,j}^{"}) + (\beta_{w,j,t}^{"} * \beta_{w,j,t} * W_{s_{w,j}}^{"}) + \delta_{w,j,t}^{"} * O_{w,j,t}^{m} \right] \\ &- (\alpha_{i,j,t}^{"} * \alpha_{i,j,t} * Iu_{i,j}^{r}) + (\beta_{i,j,t}^{"} * \beta_{i,j,t} * Iu_{i,j}^{m}) = 0 \end{split}$$

LINDO form of equation 5.3.1.1 is as follows:

$$KKBFt - \sum_{w=1}^{Zi, j} [wjSPt + (K_{w, j, t}^{"} * K_{w, j, t}) * wjIR' + (\beta_{w, j, t}^{"} * \beta_{w, j, t}) * wjWS + \delta_{w, j, t}^{"} * wjOMAt]$$

$$- (\alpha_{i, j, t}^{"} * \alpha_{i, j, t}^{"} * KKBIUMR) + (\beta_{i, j, t}^{"} * \beta_{i, j, t}^{"} * KKBIUM) = 0$$

LIMITS:

$$TI_{i,j}^{q,j_1} \le$$
 , i.e., KKBOIUC  $\le$ 

$$TE_{i,j}^{q,j_E} \le , i.e., KKBOESMS \le$$

If export is nil , i.e., NILOE

$$Iu_{i,j}^{nuth} \le$$
 , i.e., KKBIUMRH  $\le$ 

$$lu_{ij}^{n} \leq$$
 , i.e., KKBIURS  $\leq$ 

### **Equation 5.3.1.9**

Original equation 5.3.1.9 is as follows:

$$Ft_{i_t,j_t} = \sum KKBF_t$$

LINDO form of equation 5.3.1.9 is as follows:

### Equation 5.3,1.10

Original equation 5.3.1.10 is as follows:

$$OT_{i,j} = \sum KKBO_t$$

LINDO form of equation at 5.3.1.10 is as follows:

### Equation 5.31.2

Original equation 5.31.2 is as follows:

$$O_{i,j,t}^{m} - 0.01 * I_{i,j,t} = 0$$

LINDO Form of equation 5.3.1.2 is as follows:

$$KKBOMt - 0.01KKBIt = 0$$

### Equation.5.3.1.3

Original equation.5.3.1.3 is as follows:

$$Iu_{i,j}^{mh} + Iu_{i,j}^{ml} - Iu_{i,j}^{m} = 0$$

LINDO Form of equation 5.3.1.3 is as follows:

KKBIUMH + KKBIUML - KKBIUM = 0

Original equation 5.3.1.4 is as follows:

$$lu_{i,\,j}^{\,rg} + lu_{i,\,j}^{\,rs} - lu_{i,\,j}^{\,r} = 0$$

LINDO Form of equation 5.3.1.4 is as follows:

KKBIURG + KKBIURS - KKBIUR = 0

## Equation 5.3.1.5

Original equation 5.3.1.5 is as follows:

$$Iu_{i,j}^{rg} \le Og_{i,j}^{us} - (Iu_{i,j}^{ml} + Iu_{i,j}^{mhg})if - ve = 0$$

LINDO Form of equation 5.3.1.5 is as follows:

KKBIURG <= KKBOGUS - KKBIUML - KKBIUMHG, IF, -VE; =0

# **Equation 5.3.1.6**

Original equation 5.3.1.6 is as follows:

$$Iu_{i,i}^{mhg} - 0.5Iu_{i,i}^{mh} = 0$$

LINDO Form of equation 5.3.1.6 is as follows:

KKBIUMHG - 0.5KKBIUMH = 0

# **Equation 5.3.1.7**

Original equation 5.3.1.7 is as follows:

$$Iu_{i,i}^{mhs} - 0.5Iu_{i,i}^{mh} = 0$$

LINDO Form of equation 5.3.1.7 is as follows:

KKBIUMHS - 0.5 KKBIUMH = 0

## IV.3.2. Storage Limits Constraints

### Equation 5.3.2

Original equation 5.3.2 is as follows:

$$Yd_{i,j} \leq min_{i,j,t} \leq S_{i,j,t-1} \leq Ymax_{i,j,t} \leq Y_{i,j}$$

LINDO form of equation 5.3.2 is as follows:

### IV.4 RESERVOIR RELEASE CONSTRAINTS

### Equation 5.3.3.1

Original equation 5.3.3.1 is as follows:

$$O_{i,j,t} + I_{i,j,t}^{n} = Od_{i,j,t} + Sp_{i,j,t}$$

Rearranged equation 5.3.3.1 is as follows:

$$Od_{i,j,t} + Sp_{i,j,t} - O_{i,j,t} = I_{i,j,t}^*$$

LINDO form of equation 5.3.3.1 is as follows:

$$KKBODt + KKBSPt - KKBOt = KKBIt$$

## **Equation 5.3.3.2**

Original equation 5.3.3.2 is as follows:

$$\operatorname{Od}_{i,j,t} = \operatorname{Od}_{i,j,t}^{r} + \operatorname{Od}_{i,j,t}^{m}$$

Rearranged equation 5.3.3.2 is as follows:

$$Od_{i,i,t} - Od_{i,i,t}^{r} - Od_{i,i,t}^{m} = 0$$

LINDO form of equation 5.3.3.2 is as follows:

$$KKBODt - KKBODRt - KKBODMt = 0$$

#### Equation 5.3.3.3

Original equation 5.3.3.3 is as follows:

$$Og_{i, j, t}^{r} = K_{i, j, t} * Ir_{i, j}^{g}$$

Rearranged equation 5.3.3.3 is as follows:

Og 
$$_{i, j, t}^{r} - K_{i, j, t}^{s} * Ir_{i, j}^{s} = 0$$

LINDO form of equation 5.3.3.3 is as follows:

$$KKBOGRt - K_{i,j,t} * KKBIRG = 0$$

# **Equation 5.3.3.4**

Original equation 5.3.3.4 is as follows:

Od 
$$_{i,j,t}^{r} = K_{i,j,t} * Ir_{i,j}^{s}$$

LINDO form of equation 5.3.3.4 is as follows:

$$KKBODRt - K_{i,i,i} * KKBIRS = 0$$

Original equation 5.3.3.5 is as follows:

$$\mathrm{Og}^{\mathfrak{m}}_{i,j,t} = \xi_{i,j,t}(\phi^{U^g}_{i,j}\mathrm{Ws}^{U}_{i,j} + \phi^{I^g}_{i,j}\mathrm{Ws}^{I}_{i,j})$$

Rearranged equation 5.3.3.5 is as follows:

$$Og_{i,j,t}^{m} - \xi_{i,j,t}(\phi_{i,j}^{U^{g}}Ws_{i,j}^{U} + \phi_{i,j}^{I^{g}}Ws_{i,j}^{I}) = 0$$

LINDO form of equation 5.3.3.5 is as follows:

KKBOGMt - 
$$(\xi_{i,j,t} * \phi_{i,j}^{U^*} * KKBWSU) - (\xi_{i,j,t} * \phi_{i,j}^{I^*} * KKBWSI) = 0$$

### LIMITS:

Ws 
$$_{i,i}^{U} \leq$$
, i.e., KKBWSU  $\leq$ 

Ws 
$$\frac{1}{i,j} \le$$
, i.e., KKBWSI  $\le$ 

### **Equation 5.3.3.6**

Original equation 5.3.3.6 is as follows:

$$Od_{i,j,t}^{m} = \xi_{i,j,t}(\phi_{i,j}^{U^{s}}Ws_{i,j}^{U} + \phi_{i,j}^{I^{s}}Ws_{i,j}^{1})$$

Rearranged equation 5.3.3.6 is as follows:

Od 
$$_{i,j,i}^{m} - \xi_{i,j,i} (\phi_{i,j}^{U^{s}} Ws_{i,j}^{U} + \phi_{i,j}^{I^{s}} Ws_{i,j}^{I}) = 0$$

LINDO form of equation 5.3.3.6 is as follows:

KKBODMt-
$$(\xi_{i,j,t} * \phi_{i,j}^{U^*} * KKBWSU) - (\xi_{i,j,t} * \phi_{i,j}^{I^*} * KKBWSI) = 0$$

LIMITS:

Ws 
$$_{i,j}^{U} \le$$
 , i.e., KKBWSU  $\le$ 

$$Ws_{i,j}^{I} \leq , i.e., KKBWSI \leq$$

# **Equation 5.3.3.7**

Original equation 5.3.3.7 is as follows:

$$\operatorname{Ir}_{i,j}^{'} = \operatorname{Ir}_{i,j}^{8} + \operatorname{Ir}_{i,j}^{8}$$

Rearranged equation 5.3.3.7 is as follows:

$$Ir_{i,j}^{i} - Ir_{i,j}^{s} - Ir_{i,j}^{g} = 0$$

LINDO form of equation 5.3.3.7 is as follows:

# **Equation 5.3.3.8**

Original equation 5.3.3.8 is as follows:

$$Ws'_{i,j} = Ws^{u}_{i,j} + Ws^{I}_{i,j}$$

Rearranged equation 5.3.3.8 is as follows:

$$Ws_{i,i} - Ws_{i,i}^{U} - Ws_{i,i}^{I} = 0$$

LINDO form of equation 5.3.3.8 is as follows:

$$KKBWS'-KKBWSU-KKBWSI=0$$

#### 1.5 GROUND WATER AVAILABLILITY CONSTRAINTS

# Equation5.3.4-1

Original equation 5.3.4-1 is as follows:

$$\sum_{t} Og \ ^{m}_{i,j,\,t} + \sum_{t} Og \ ^{r}_{i,\,j,\,t} = Og \ ^{ds}_{i,\,j} \quad \text{for each } i,\,j \text{ and } t.$$

LINDO form of equation is as follows:

$$\sum$$
 KKBOGMt +  $\sum$  KKBOGRt = KKBOGDS

Not to be used equations 5.4-2 & 5.4-3

For each i and j.

# **Equation 5.3.4-2**

Original equation 5.3.4-2 is as follows:

$$Iu_{i, j}^{m, g} + Iu_{i, j}^{r, g} = Og_{i, j}^{us}$$

LINDO form of equation is as follows:

# **Equation 5.3.4-3**

Original equation 5.3.4-3 is as follows:

Og 
$$\underset{i, j}{us}$$
 + Og  $\underset{i, j}{ds}$  = Og  $\underset{i, j}{i}$  for each i and j.

LINDO form of equation is as follows:

### IV.6 SUB-BASINWISE ANNUAL IRRIGATION CONSTRAINTS

### **Equation 5.3.4.1**

Original equation 5.3.4.1 is as follows:

OC 
$$\frac{r}{i, j} = \sum_{t=1}^{12} \frac{r}{0d}$$

Rearranged equation 5.3.4.1 is as follows:

OC 
$$\begin{bmatrix} \mathbf{r} \\ \mathbf{i}, \mathbf{j} \end{bmatrix} - \begin{bmatrix} 12 \\ \sum \mathbf{Od} \end{bmatrix} = 0$$

LINDO form of equation 5.3.4.1 is as follows:

$$KKBOCR - \Sigma(KKBODRt) = 0$$

# IV.7 SUB-BASINWISE ANNUAL WATER SUPPLY CONSTRAINTS

# Equation 5.3.6

Original equation 5.3.6 is as follows:

$$OC_{i, j}^{m} = \sum_{t=1}^{12} Od_{i, j, t}^{m}$$

Rearranged equation 5.3.6 is as follows:

OC 
$$\lim_{i, j} - \sum_{t=1}^{12} 0d^{m}_{i, j, t} = 0$$

LINDO form of equation 5.3.6 is as follows:

KKBOCM - 
$$\Sigma$$
KKBODMt =0

# IV.8 SUB-BASINWISE CANAL CAPACITY CONSTRAINTS

#### Equation 5.3.7

Original equation 5.3.7 is as follows:

$$(OC_{i,j}^r + OC_{i,j}^m) - CC_{i,j} \le 0$$

Rearranged equation 5.3.7 is as follows:

$$(OC_{i,j}^r + OC_{i,j}^m) - CC_{i,j} \le 0$$

LINDO form of equation 5.3.7 is as follows:

LIMITS:

$$CC_{i,j} \leq$$
, i.e., KKBCC  $\leq$ 

### IV.9 LAND USE CONSTRAINTS

# Equation 5.3.8

Original equation 5.3.8 is as follows:

$$\lambda_{i,j,t}^{k} * A_{i,j}^{k} \leq TA_{i,j}$$

Rearranged equation 5.3.8 is as follows:

$$\lambda_{i,j,t}^{k} * A_{i,j}^{k} - TA_{i,j} \leq 0$$

LINDO form of equation 5.3.8 is as follows:

$$\lambda_{i,j,t}^{k} * KKBA_{i,j}^{k} - KKBTA_{i,j}^{k} \le 0$$

# IV.10 CROP WATER REQUIREMENT CONSTRAINTS

# Equation 5.3.9

Original equation 5.3.9 is as follows:

$$W_{i,j,t}^{k} * A_{i,j}^{k} \le K_{i,j,t} * Ir'_{i,j}$$

Rearranged equation 5.3.9 is as follows:

$$W_{i,j,t}^{\,k} * A_{i,j}^{\,k} - K_{i,j,t}^{\,\,*} * Ir_{i,j}^{\,\,*} \leq 0$$

LINDO form of equation 5.3.9 is as follows:

$$W_{i,j,t}^{k} * KKBA - K_{i,j,t} * KKBIRD \le 0$$

### **PUBLICATION**

A paper presented during the present study is reported as follows:

Patil, M. D., Sharma, N. and Ojha, C.S.P., "A Case Study of Transbasin Water Transfers Possibilities Between the Godavari and the Krishna Basin in India", presented at USCID International Conference on Transbasin Water Transfers, conducted by UNITED STATES COMMITTEE ON IRRIGATION AND DRAINAGE (USCID), 1616 Seventeenth Street, Suite 483, Denver, Colorado, U.S.A. June 26-30, 2001.
